ENCYCLOPÆDIA BRITANNICA.

PLATA, LA.

LA PLATA is the name of an extensive tract of country in South America, extending from the eastern declivities of the Chilian Andes, to the great rivers Paraguay, Parana, and La Plata. During the latter period of Spanish domination, it formed the viceroyalty of the Rio de la Plata, or Buenos Ayres, having then annexed to it Bolivia or Upper Peru, Paraguay, and the Banda Oriental. By subsequent changes these have been erected into independent states, and the remaining territory has been constituted a republic under the name of the Argentine Republic, or the United Provinces of the Rio de la Plata. It is a federal state, consisting of a number of provinces, of which Buenos Ayres is the head. Before describing this country, we shall briefly glance at its past history.

To the Spaniards belongs the honour of first discovering this part of the South American continent. In the year 1515, Juan Dias de Solis or Salis, having been furnished by the court of Spain with two ships for the purpose of exploring Brazil, arrived, on his voyage thither, at the mouth of the Rio de la Plata. Touching on the north coast between Maldonado and Monte Video, he took formal possession of the land in name of his sovereign; but, thrown off his guard by the deceitful friendship of the natives, he was slain, along with a few attendants who had followed him on shore. The coast was immediately abandoned by the survivors on board of the vessels; but in the year 1526 a fresh expedition, under the celebrated Sebastian Cabot, then in the service of Spain, entered the river, and cast anchor opposite the present site of Buenos Ayres. This took place at the time when a Spanish captain called Garcia was making discoveries in other parts of the same river. Advancing about a hundred and twenty leagues upwards, Cabot discovered a fine river flowing into the main stream. Up this he sailed with his fleet, and disembarking his men, built a fort, in which he left a garrison; whilst he himself, with his remaining followers, pursued his discoveries still farther up the river. The Indians with whom he came in contact exhibited abundance of gold and silver plates, particularly the latter, brought by them from the eastern parts of Peru; but the circumstance led Cabot to believe that mines of the precious metals existed in the country in which he then was, and accordingly he gave the name of Rio de la Plata, or River of Silver, to the noble stream by which it was watered. The Spaniards soon determined on colonizing this valuable acquisition; and, to prevent any interference on the part of the other nations of Europe, Don Pedro de Mendoza, with two or three thousand followers, was sent from Spain to secure the possession, and establish a relationship between it and the mother country. He landed upon the western shore of the La Plata in the year 1535, and founded the city of Buenos Ayres, which he so named from the salubrity of the climate. Pursuing his way into the interior, he conquered all the country as far as Potosi, at which mines of silver were discovered nine years afterwards. The first settlers at Buenos Ayres were most unfortunate; their town was burned by the Indians, and after suffering every privation, they were shortly afterwards compelled to abandon the place. Previously to this event, Assumption, the capital of Paraguay, had been founded; and thither the wretched remains of the expedition retreated. A second armament was fitted out, and an attempt made to rebuild the town, in 1542; but it was overwhelmed by a calamity similar to that which had overtaken the former. The chief attention of the Spaniards was for some time directed to forming settlements in Paraguay, in order to facilitate their communication with the mines of Peru, where Pizarro and his successors were gathering in a golden harvest. Contentions with the Indians were frequent and bloody, for the inhabitants of the vast plains upon either bank of the La Plata proved much more difficult to subdue than the timid and tractable Peruvians.

It was not until the year 1580 that the Europeans succeeded in their attempts to found a town upon the site chosen by Mendoza. Before this period, however, they had established themselves at Santa Fe, Mendoza, and some other places in the interior; so that, as Dr Southey observes, the history of this part of South America differs from that of any other colony in one remarkable circumstance: The first permanent settlement was formed in the heart of the country, and the Spaniards colonized from the interior towards the sea. But they were not permitted quietly to enjoy the success of their third attempt to found Buenos Ayres.

Stimulated by the recollection of their previous triumphs in demolishing the works of the invaders on the same ground, the Indians once more attacked it, and were so far successful as to set fire to the tents and temporary erections of the settlers. Their leader, however, being slain, they were compelled to retreat with loss; and before they were in a condition to renew the work of demolition, the town was so well fortified and garrisoned as to bid defiance to their efforts. Again the leader of the savages fell, and his force was completely defeated and put to flight. From this period the city began to prosper, and the ship which carried to Castille the intelligence of its refoundation took home a cargo of sugar, and the first hides with which Europe was supplied from the wild cattle which now began to overspread the country, and soon produced a total change in the manners of all the adjoining tribes. The immense pampas of La Plata appear to have been originally stocked with cattle from a few which had been brought by the earliest settlers; and so rapidly had they multiplied, that, about the year 1610, no less than a million is said to have been driven from the country in the neighbourhood of Santa Fe into Peru.

In the year 1620 Buenos Ayres was erected into a bishopric; but for nearly two centuries it continued to be a place of little note, and comparatively scanty population. From the first period of the colonization of this country till the year 1778, the government was dependent on that of Peru, although the chief of Buenos Ayres had the title of captain-general. A false idea of what constitutes wealth led Spain to estimate the value of her possessions by the number and richness of their mines of gold and silver; and Buenos Ayres being deficient in these, its more solid advantages of a fertile soil and a salubrious climate were consequently overlooked. The pernicious system of political economy practised by Spain towards her colonies was the main cause why this city remained for such a length of time almost entirely unknown to Europeans. Apprehensive lest commodities might be introduced into Peru by way of Buenos Ayres, and thus prejudice the sale of the cargoes imported by the fleets which they sent to Panama, the early traders solicited and obtained from the government the prohibition of every kind of commerce by the Rio de la Plata. Those whom this measure most nearly affected put in a strong remonstrance against it, and were so far successful that, in 1602, permission was granted them to export for six years, in two vessels belonging to themselves, and on their own account, a certain quantity of flour, tallow, and jerked beef, but only to two ports. Upon the expiration of the term an indefinite prolongation was solicited, with an extension to all kinds of merchandise, and liberty to trade also with other ports. This application was vehemently opposed; but notwithstanding, in the year 1618, the inhabitants of the shores of the Rio de la Plata were authorized to fit out two vessels, not exceeding one hundred tons burden each. Several other vexatious restrictions were imposed on them; and, to prevent any traffic with the interior of Peru, a custom-house was established at Cordova del Tucuman, where a duty of fifty per cent. was levied upon all imports. This custom-house was also designed to prevent the transmission of the precious metals from Peru to Buenos Ayres, even in payment for mules furnished by the latter city. By an order of 1622 this permission was prolonged for an indefinite period; and, with a view to promote the prosperity of the country, a royal audience was established at Buenos Ayres in 1665.

Under such a miserable system of policy, it is not surprising that the provinces of the Rio de la Plata languished in indigence and obscurity. But the resources of so extensive and fertile a territory could not remain for ever concealed. As the population and wealth of the country increased, the continual remonstrances of the people at last opened the eyes of the Spanish government to the importance of the colony, and a relaxation took place in the system of commercial monopoly, which had hitherto been rigorously adhered to. Indeed the absurd restrictions had been followed by their natural consequence, smuggling; and to such a height was the contraband trade carried, that, in order to put a stop to it, the government of Castille gave permission to register ships to sail under a license from the council of the Indies at any time of the year. The flota which hitherto had embarked from Spain once a year, and was the only legitimate means of communication with America, dwindled away from 15,000 to 2000 tons of shipping; and in 1748 it sailed for the last time to Cadiz, after having carried on the trade of Spanish America for two centuries. The register-ships now supplied the market with European commodities at a cheaper rate and at all seasons of the year; and from that time Buenos Ayres gradually rose into importance. Other relaxations in the mercantile system followed soon afterwards. In the year 1774 a free trade was permitted between several of the American ports; and this was subsequently followed by additional liberties.

The improvements which took place in Buenos Ayres by this enlargement of its commercial relations were frequently interrupted by circumstances which carry us back to an early period of its history. The Spaniards and Portuguese have, by a singular coincidence, been destined to be rivals, not only in the Old, but in the New World. The neighbouring territory of Brazil belonged to Portugal, and bitter hostilities frequently took place between the two countries. It is computed that, in the hostile incursions which the Brazilians made into the Spanish possessions in this quarter of America, they destroyed upwards of four hundred towns and villages. These marauders, born of Portuguese, Dutch, French, Italian, and Brazilian women, were called Mamelucos. Their principal object was to carry into slavery the Indians whom the Jesuits had partially civilized; and in exercising their inhuman trade they committed the most horrid enormities. It is asserted, that in one hundred and thirty years two millions of Indians were slain or carried into captivity by the Mamelucos of Brazil, and that more than one thousand leagues of country, as far as the river Marañon, were almost depopulated. It may well be believed that the settlements of the Rio de la Plata did not escape the same cruel devastation. But it does not appear that the acts of these marauders were authorized by the government which they professed to obey; for repeated decrees were passed in favour of the oppressed Indians. These, however, were seldom or never observed; and governors and others, who profited by the captivity and sale of the native tribes, winked at the traffic. But the rivalry and animosity of the Portuguese were productive of other evils besides those consequent on hostile incursions. We have alluded to an extensive contraband trade, originating, in the first instance, in the blind policy of Spain. This was chiefly carried on by the Portuguese, who were enabled, by means of the immense and thinly-inhabited territory of the Banda Oriental, to organize a system of smuggling which ultimately almost annihilated legitimate commerce. But the government having gained over Artigas, one of the most daring of the contrabandists, were at length enabled, with his assistance, to crush the illicit trade, and to put an end to the atrocities which it had inflicted on the country.

In the year 1778, the provinces of the Rio de la Plata, Paraguay, Tucuman, Los Charcos, and Chiquito, were erected into a viceroyalty, of which Buenos Ayres was constituted the capital. At the same time it was thrown open to free trade of every description, even with the interior of Peru; and such was the effect of this wholesome measure, that the number of vessels trading with South America was at once augmented from fifteen to one hundred and seventy. They kept gradually increasing from year to year; and, in 1796, sixty-three vessels from Old Spain alone arrived in the single port of Buenos Ayres, with cargoes valued at nearly three millions of piastres; and fifty-one sailed from it for the mother country, fourteen to the Havannah, and eleven to the coast of Africa. The value of the exports was about five millions and a half of piastres, including upwards of four millions in gold and silver. During the war which broke out between Great Britain and Spain, the trade of this colony suffered severely; indeed for a time it was all but annihilated. Immense quantities of hides and other native productions, pent up in the warehouses of Buenos Ayres and Monte Video, were allowed to rot, there being no outlet for them; whilst at the same time many kinds of European goods rose to exorbitant prices, or were not to be procured at any cost. This situation of affairs afforded the people of the United States of North America an opportunity of carrying on a contraband trade, by which the inhabitants of the provinces of the Rio de la Plata were supplied with European commodities; and this traffic was connived at by the Spanish government. The fortune of war, however, in a few years placed Buenos Ayres for a short time in the hands of the British, and an end was put to the trade with the great western republic.

In the year 1806, a British squadron, under the command of Sir Home Popham, appeared in the Rio de la Plata. From this armament a body of troops was landed, for the purpose of taking the capital. The British force was small, but, by the culpable negligence of the viceroy, the Marquis de Sombre Monte, who does not appear to have made any attempt to defend this important city, General Beresford accomplished his object on the 26th of June. This rash and unauthorized enterprise was fortunate in the first instance, but exceedingly disastrous in its issue. The viceroy having retired to Cordova, Don Santiago Liniers, a Frenchman in the service of Spain, put himself at the head of all the troops he could collect on both banks of the Plata, and on the 12th of August attacked the city at several points. So vigorous and successful was the assault, that the British general and his troops were compelled to surrender themselves prisoners of war. The disgraceful retreat of the viceroy having completely alienated from him the esteem of those over whom he ruled, they accordingly stripped him of his authority, and made the most strenuous efforts to obtain the office for Liniers, but without success. He was covered with honours, but a new viceroy arrived from Spain. Never was there a more favourable opportunity for these provinces entirely throwing off the yoke of the mother country; but no spirit of revolt existed in the country. The fact is, that, at the period of this invasion, Spain nowhere possessed more faithful subjects than those who peopled the banks of the Rio de la Plata. There cannot be a doubt, however, that this successful repulse of an enemy common to both, taught the people of Buenos Ayres "a deep lesson;" and it ought to be regarded as the first step to that revolution in which the power of Spain in America was completely overthrown.

In the mean time, British reinforcements arrived from the Cape of Good Hope, whence the original expedition had sailed; and Sir Home Popham, after making an unsuccessful attempt on Monte Video, took Fort Maldonado, at the mouth of the river Plata. But the intelligence of the first capture of Buenos Ayres was so well received by the British public, that government resolved on maintaining possession of the banks of the Plata; and an armament was therefore fitted out for effectually reducing the country. The first body of troops, which were commanded by Sir Samuel Auchmuty, enabled the British to undertake the conquest of Monte Video, which was carried by storm in February 1807. In May following, General Whitelocke arrived at the head of a formidable force; and about a month afterwards these were joined by a further reinforcement under General Crawford. The army now amounted to 8000 men, and the chief command was confided to General Whitelocke, a man destitute alike of courage and ability. The reduction of Buenos Ayres was now resolved upon; but if the British had acquired sufficient local and political knowledge of the country, they would never have attempted the conquest of that city. The attacking army sailed up the river, and, disembarking below the capital, marched towards it, but met with a reception which was little anticipated. The inhabitants of Buenos Ayres had made every preparation for a desperate resistance. The streets were intersected by deep ditches, defended by cannon, and the windows and house-tops were thickly planted with armed men. No sooner had the British troops begun to penetrate the streets in columns, than they were assailed by grape and musketry, under which they perished in great numbers, without being able to retaliate on the citizens. The cool, determined valour of the troops, and the heroic energy of the leaders of the several columns, were exerted in vain. About one third of the British army was either killed, wounded, or taken prisoners, without any material advantage having been gained. In these circumstances, it would have been madness to persist in such a mode of operation; and next day an armistice was concluded. A convention followed, the terms of which were, that the British should evacuate the possessions on the Plata in two months, and that all prisoners taken on both sides should be restored. By this capitulation, Monte Video, which might have been safely maintained against any enemy, and which would have afforded a secure dépôt for our manufactures, was also lost.

But the events which were now passing on the continent of Europe were destined to change completely the aspect of affairs in South America. The unprincipled invasion of Spain by Napoleon in 1808 had placed that country in a situation extremely critical. Ferdinand VII., in concert with the emperor, had intrigued to wrest the sceptre from the feeble hands of his father; the French everywhere overran the Peninsula, and numerous petty juntas were formed. These began to extend their authority to the colonies, and despatched several mandates to the New World, demanding implicit obedience to the resolutions which they contained. As far as possible, the provinces of the Rio de la Plata conformed to their dictates, and sent money and supplies of various kinds to repel the attempts of the French, a nation peculiarly offensive to them.

Whilst the public mind at Buenos Ayres was thus kept in a state of excitement by the aggression of Napoleon, the transfer of the court of Lisbon to the Brazils inspired the princess regent of Portugal with the ambition of establishing herself in a similar manner at Buenos Ayres. Her father and her brother having at Bayonne renounced their right to the crown of Spain, she despatched emissaries to La Plata to assert her contingent claim, and to concert measures for her residence in the capital. Her proposals were received with enthusiasm, not only by the people, but also by the most influential persons of the country. But when her projects were on the point of being crowned with success, they were rendered abortive by the arrival, in May 1809, of the viceroy Cisneros, who, having touched at Monte Video in ascending the river Plata, there concerted measures with the governor-general, Elio, who, like himself, was a staunch supporter of the rights of Ferdinand. In the mean time Napoleon, having turned his attention to the colonies of Spain, had, like the princess already mentioned, sent an emissary to Buenos Ayres to gain over the inhabitants. Liniers, whom the course of events had brought prominently forward, is said to have secretly favoured the interests of France; but he was deposed from all authority, and banished to Cordova. In no instance was Napoleon successful in seducing the American colonies from

La Plata.

La Plata.

Spain, although it is perfectly evident that the doubtful nature of their allegiance, thus brought palpably before them, was well calculated to afford a plausible pretext for their adopting measures to secure their own individual independence, should circumstances hold out a well-grounded hope of success. These were not long in arriving.

Cisneros, the new viceroy, exerted himself to the utmost to fulfil the orders of the court of Madrid, and to close the ports of the Plata against British traders, who, in spite of reiterated prohibitions, continued to land their goods. An intelligent native of the name of Don Mariano Moreno addressed a pamphlet to the viceroy, demonstrating the necessity of re-modelling antiquated institutions, no longer compatible with national prosperity. The enlightened views of Moreno, though strongly opposed by the privileged merchants of Cadiz and Buenos Ayres, were generally favoured by his countrymen, and the necessity of a relaxation of the prohibitory system, as the only means of replenishing the exhausted treasury, at length compelled the reluctant acquiescence of Cisneros.

From this period the principal supporters of the Princess Carlota changed their views, and formed plans of ultimately setting up the standard of independence. After some political struggles, they succeeded in deposing the viceroy, and, on the 25th of May 1810, named a *junta gubernativa*, composed of nine members, with Don Cornelio de Saavedra as their president, and Dean Funes and Don Mariano Moreno as their secretaries.[1]

Moreno, the secretary, possessing a genius fitted for the times, became the life and soul of the new government. As the eyes of the people in the provinces were opened to the daring nature of the step which had been taken, the authority of the junta became more and more circumscribed, and was soon reduced to the limits of Buenos Ayres. Monte Video did not recognise it at all. As the port of this city contained a naval dépôt, there were there concentred a greater number of civil and military officers, who, being Spaniards, immediately took alarm, and decisive measures were adopted to prevent the heresy from spreading beyond the limits of Buenos Ayres, if not to crush it there. But the Creoles viewed the matter very differently. They assembled at the municipality, and unanimously resolved that it was expedient to join the party in the capital. But this wise resolution was rendered abortive by the precaution of the governor, Elio, and by the address and intrigue of an individual, Dr Obes by name, whose ambition was the original cause of the misfortunes which befell the Banda Oriental. He succeeded in drawing over many of his countrymen to his own views; and ultimately an answer was transmitted to Buenos Ayres, the purport of which was, that the Monte Videans could not give in their allegiance to an authority not appointed in a legitimate way by the nation. But Moreno was nothing dismayed by this intelligence, and his measures became more decisive as the emergency increased. He succeeded in expelling the viceroy and the oidores from the country; and had not the junta itself become infected by schism, such a man at the head of affairs would have soon brought matters to an issue. It became impossible for the junta to exist in its then disjointed state. Moreno and his party withdrew; and he having accepted a mission to England, unfortunately died on his passage.

The people of Buenos Ayres having so far succeeded in establishing their independence, considered themselves powerful enough to proselytize in the provinces. A division of patriots under Ocampo was sent against Cordova, where a formidable faction opposed to the new order of things had been organized by Liniers; and this leader was taken prisoner and shot, along with several other influential persons. Such severe measures, however, not harmonizing with the moderate views of Saavedra and the junta, Ocampo was recalled, and the chief command intrusted to Don Antonio de Balcarce. The history of La Plata is now for some years closely interwoven with that of Upper Peru. In September 1811 the junta gubernativa at Buenos Ayres was dissolved, and Saavedra the ex-president compelled to fly. An executive was thereupon vested in the hands of a triumvirate, Don Manuel Sarratea being its head. Monte Video still stoutly maintained the sinking cause of Spain; the effort was unavailing. Twice the soldiers of the fortress, in attacking the soldiers of Buenos Ayres, were driven back. In one of these the noted Artigas displayed his characteristic heroism, and at the head of his brave Gauchos performed prodigies of valour in the patriot cause. But he had long displayed symptoms of insubordination. About this period he withdrew from the command of Rondeau, and, in acting independently, evinced ever afterwards great dislike to the inhabitants of Buenos Ayres. In October 1812 another change was effected in the government, and in the January following a sovereign constituent assembly was convened at Buenos Ayres. It was not until now that the Spanish flag and cockade were abolished, and replaced by the bicolor. Now also the coinage bore the republican arms. The assembly elected an executive consisting of three individuals, and Don Carlos Alvear was chosen president of the assembly. But this form of government was as short-lived as any that had preceded it. On the 31st of December 1813 it was abolished, and Señor Posadas was elected supreme director of the republic, with a council of seven to act along with him.

Monte Video, which still held out for the mother country, was soon afterwards taken, when between 5000 and 6000 royalist troops laid down their arms, and an immense quantity of military stores was likewise given up. But the refractory Artigas, who had assumed the title of chief of the Banda Oriental, demanded possession of the place, which being refused, he in a short time took it by force, and retained possession of the fortress until a Brazilian army ejected him in the year 1817. The mutations and changes which the government of Buenos Ayres underwent we need not follow; and the civil dissensions by which the country was afflicted are equally endless and uninteresting. In 1816 a new congress met at Tucuman, which named Pueyrredon director of the republic; in July it declared the countries on the Plata independent, and, having transferred its sessions to Buenos Ayres, issued a declaration,[2] containing a list of twenty-eight articles. This remarkable document describes the cruelties which the united provinces of the Rio de la Plata, as well as other parts of America, had endured, whilst under the yoke of Spain, and the motives which led them to shake it off.

The republic now assumed the title of the United Provinces of South America, and on the 3d of December 1817 it proclaimed a *reglamento provisorio*, as preliminary to a constitution. The congress chosen in compliance with the *reglamento* was opened in February 1819, and on the 25th of May the new constitution was published; but it afterwards underwent many important changes. It was on the model of that of the United States, and secured personal freedom and equality, liberty of conscience and of the press, and the right of suffrage. The country, however, still continued in a disturbed state, and these troubles were increased by the intrigues of France and Austria to impose upon the natives of Buenos Ayres a Bourbon or an Austrian prince; but the latter were happily defeated by the good sense and patriotism of the people, notwithstanding the anarchy which had reduced them to the brink of destruction. To enumerate the factions which successively got the upper hand at Buenos Ayres, or to describe their various intrigues to maintain themselves in power, would be to draw a most disgusting picture of the reign of anarchy. Numerous successive governors seized upon office, and retained it but for a few weeks, and in some instances for a still shorter period. These rapid changes were generally preceded by sanguinary struggles, and followed by banishments and proscriptions; but in no instance was confiscation of property resorted to, so far had public opinion wrought an improvement. In October 1833 an attempt was made to effect a revolution in Buenos Ayres, and in June of the year following the government resigned spontaneously. The internal provinces were as usual the theatre of petty dissensions and skirmishes. In March 1835 the chamber elected General Don Rosas governor and captain-general of the province of Buenos Ayres for five years; giving him extraordinary powers, whilst he was at liberty to resign whenever he might judge fit, and only restricting him in one point, by obliging him to maintain and uphold the Catholic religion. The peace of the republic was disturbed throughout the year by petty insurrections, and by an attempt in the province of Tucuman to foment a revolution in favour of the Unitarians; but it was completely put down, and during the year 1836 the republic remained in a comparatively tranquil state. It is worthy of record, that on the 4th of December Spain acknowledged the independence of La Plata, and of all the other provinces in America which formerly belonged to her. Since then, up to the present time (1838), no event of any moment has occurred, with the exception of a declaration of war against Peru; but a peace was concluded between the two powers before any blood was shed on either side.

Boundaries and extent.

La Plata is situated between 20° and 38° or 39° of south latitude, and between 55° 36′ and 71° of west longitude. Its extreme length is about 1400 miles, and in breadth it varies from 500 to 800. It is bounded on the north by Bolivia; on the east by Paraguay, Uruguay, and the Atlantic Ocean; on the south by Patagonia and the Atlantic Ocean; and all along its western limits, the lofty ranges of the Andes separate it from Chili. In the north-west, the eastern declivities of the Andes project a considerable way forwards, so that this district, which comprises the provinces of Salta, Tucuman, Santiago, Mendoza, San Juan, Rioja, and Catamarca, is a high and rugged table-land. All the rest of La Plata constitutes one continuous plain, perhaps the most extensive and uniform in the whole world. The geology of this country presents little variety, and almost nothing that is interesting. Rocks are seldom seen, except in the mountainous region. Some gypsum occurs in the vicinity of Buenos Ayres, and limestone is said to occur in several places. The stones used in paving the streets, or in building, are brought from the island of Martin Garcia, at the mouth of the Uruguay, or as ballast in vessels from Europe.

Rivers.

Of the rivers, the principal is that which gives name to the region. The country, however, is traversed by several other large streams, the general bearing of which is to the south-east. Passing over the Pilcomayo, the Bermijo or Rio Grande, and the Salado, which have been described in the articles Paraguay and Parana, the next in importance is the Saladillo. The course and extent of this river are very imperfectly known. It appears to rise in the mountainous parts of Cordova, and after traversing the province of Buenos Ayres, it falls into the sea at Rosas, in the bay of Samborombon. The Tercero, which also rises in the province of Cordova, and falls into the Parana, has been proved to be navigable for barges as high as the Pass of Fereira, about thirty leagues below the city of Cordova.

Considerable light has recently been thrown on the hydrography of the southern portion of the Argentine Republic, by the publication of a journal kept by La Cruz, a Chilian gentleman, who, in the year 1806, undertook the command of an expedition which had for its object the discovery of a more direct means of communication between the southern provinces of Chili and Buenos Ayres, than the old one by Mendoza. An abridged account of the hydrographical facts which have resulted from this expedition we shall give in the language of an able writer.

" As we retrace his (La Cruz's) route, proceeding from east to west (from the frontiers of Buenos Ayres towards the Andes), the first considerable body of water which we meet with is the Desaguadero of the Diamante, in the middle of the continent, fifteen leagues north of the lake in which it terminates, and which is many leagues farther south than has been hitherto supposed. We next find, at a very short distance, the Chadileubu, which rises in the cordillera of Melalgué, and flows into the Desaguadero. Proceeding some leagues farther, we come on the Cobuleubu, or Rio Colorado, making a bold circuit eastward through the Pampas, as it descends from the Andes near Maulé, before it turns southwards to the sea. As we approach the Cordillera, we arrive at the Cudileubu and the Neuquen, the latter receiving the Tocoman and Reinguileubu, all considerable rivers, the united waters of which, under the name of Mucum-leubu, flow southwards into the Rio Negro. The Neuquen and Cobuleubu both appeared to him to be navigable downwards from the place where he crossed them.

" Respecting the Limayleubu, which La Cruz frequently made the object of his inquiries, the accounts of the Indians were positive and distinct. All concurred in stating it to be the greatest river with which they were acquainted on the eastern side of the Andes; that it was nowhere fordable, and that it received the Neuquen, Cudileubu, and all the other rivers of the Eastern Andes northwards to the sources of the Rio Colorado. It issues, according to them, from a beautiful lake called Alomini, of great size; for the cacique Manguel had travelled a day and a half along its shores. It is situated between the Cordilleras Miguen and Quenuco, and has an island in the middle of it. The river Limayleubu is small at first, but is soon swelled by the accession of a great many streams, of which the last in order, as named by the Indians, is the Naguelguapi. This river springs, they said, not from a lake, but from a morass of the same name. Besides the lake Alomini, the Indian chiefs also knew a lake called Guechulauguen, situated farther south, and the waters of which flow into the Limayleubu."[1]

This account differs somewhat from those which were previously given by Falkner the Jesuit and others, and which have found their way into all geographies, and vitiated all maps, thus giving rise to extreme confusion. The conclusions to be deduced from the statements of La Cruz we give in the language of the writer just quoted.

" Thus it appears to us to be clearly established that the main branch of the Rio Negro rises in the lake Alomini, situated in the Cordilleras, east of Villarica; and that, issuing thence under the name of Limayleubu, and being joined by numerous streams, among others by the Naguelguapi, mentioned by Falkner, it soon becomes a great river, of considerable width, and nowhere fordable. It afterwards receives the Cariguenague, coming from the north, and lower down, the Mucumleubu, itself a great river; the numerous tributaries to which were crossed by La Cruz.

---

[1] Edinburgh Review, No. cxxxi. p. 101–2.

The latter river is evidently the Sanguel, or Reed River of Falkner. These united waters proceed southwards a short way, till, meeting the southern branch of the Rio Negro, they turn eastward to the ocean."[1]

Lakes. Numerous rivers take their rise in the eastern declivities of the Andes, and, after irrigating considerable tracts of country, are either absorbed by the soil or flow into inland lakes. Amongst these may be mentioned the Rio Dolce, which originates in the lofty mountains of Tucuman, and, after watering the capital of the same name, passing near Santiago del Estero, capital of the province so named, and traversing Cordova, is lost in a salt lake situated in that province, and called " lagunas saladas de los Porongos." Lakes are distributed over the whole expanse of the Pampas, and some of them are of considerable size, one in Entre Rios being one hundred miles in length; but they cannot be said to correspond in grandeur to the other features of this region. The soil is almost everywhere impregnated with fossil salt; and the water of most of the lakes and pools is brackish and disagreeable to the taste. So plentifully is this saline matter distributed, that whole tracts of country are covered with its efflorescence. But a want of water is universally experienced; for, notwithstanding the number of lakes and inferior rivers, many of them disappear during the dry season. A growth of rushes overspreads their bottoms, serving as lairs for the pumas, who lie in wait for the cattle that, perishing of thirst, fly to the green stagnant water which lies on the marly surface, is as thick as refuse oil, and swarms with myriads of mosquitos.

Soil. The soil of this vast territory is a rich mould, perfectly free from stones, not one being seen on its surface for many hundred miles together. Though an uninteresting level, devoid of picturesque scenery, it is divided into regions different in climate and in produce. On leaving Buenos Ayres, and proceeding in a westerly direction, the first of these regions is covered for the space of 180 miles with clover and thistles, or artichokes; the second region, which extends for 450 miles, produces grass; and the third, which reaches the base of the cordillera, is a grove of low trees and shrubs. The first region varies in a striking manner with the seasons of the year. In winter the leaves of the thistles are large and luxuriant, and the whole surface of the country has the rough appearance of a turnip field. The clover in this season is extremely rich and strong, and amongst it the wild cattle graze at liberty. In spring the clover disappears, the leaves of the thistles droop along the ground, and the country has still the appearance of a rough crop of turnips. But in less than a month the whole region becomes a luxuriant wood of thistles in full bloom, and reaching ten or even eleven feet in height. Summer, however, is not over before another change takes place. The thistles suddenly lose their verdure and sap, their heads droop, the stems become black and dead, and being levelled by the pampero or hurricane, they are rapidly decomposed, when the clover rushes up, and all again becomes a sea of verdure. The second and third of these regions present nearly the same appearance throughout the year; for the trees and shrubs are evergreens, and the immense plain of grass only changes its colour from green to brown. Not a weed is to be found throughout its vast extent; and over its ever-verdant and luxuriant surface innumerable herds of cattle range at large. The region of wood is equally remarkable. The trees are not crowded; but in their growth such beautiful order is observed, that the traveller can gallop between them in every direction.[2]

Climate. The tropical climate which prevails in the northern districts disappears more and more towards the south, so that snow and ice are not unknown. Upon the east coast the air is humid; rain, thunder, and violent storms are not unfrequent; but in the western district the atmosphere is so free from vapour, that at mid-day the planet Venus is often distinguishable in the heavens, and the drought is so great that dead bodies are actually parched into mummies. The climate of the Pampas is subject to a great difference of temperature in winter and summer, although the gradual changes are very regular. The winter is about as cold as November is in England, and the ground at sunrise is invariably covered with white frost; but the ice is very thin. In summer the sun is oppressively hot; and not only is manual labour suspended during the middle of the day, but even the wild horses and cattle are exhausted by it. The only great irregularity in the climate is the pampero, or south-west wind, which sweeps these plains with a velocity and a violence which it is impossible to withstand. These periodical visitations, however, produce beneficial effects, the weather being particularly agreeable after they have exhausted their fury; and, taken as a whole, the Pampas may be said to enjoy as beautiful and as salubrious an atmosphere as the most healthy parts of Greece and Italy, and without being subject to malaria. With regard to humidity, the atmosphere is not uniform at places under the same latitude. In the provinces of Mendoza and San Luis, or in the regions of wood and grass, the air is very dry, and there is no deposition of dew at night. But in Buenos Ayres a considerable quantity of moisture prevails in the atmosphere, probably from the vicinity of the place to the ocean.

Productions. The productions are gold and silver, copper, tin, lead, and iron (of which large masses are often found), saltpetre, selenite (which is used instead of glass for windows and lanthorns), marine salt, barrero (a loam impregnated with salt, and greedily devoured by sheep and oxen); and there are also numerous mineral springs, besides the saline lakes already mentioned, from which salt can be procured. In some parts of La Plata there are wooded tracts consisting of palms, cedars, and other trees; but from the Rio de la Plata to the Straits of Magelhaens, as well as throughout the most part of the Pampas, we find neither tree nor shrub. Of fruits there are sugar, vines, and others; of grains, wheat and maize are especially cultivated; melons, pumpkins, beans, potatoes, and vegetables of all sorts, are raised; as also rice, manioc, and a shrub resembling aloe, from the fibres of which ropes and cordage are made; ricinus, earth almonds, flax, hemp, rhubarb, indigo, vanilla, ipecacuanha, tobacco, cotton; monkshood, with which the Indians poison their arrows; St John's wort, capaiva, and others.

Animals. This country has long been celebrated for the abundance of its cattle, oxen, horses, sheep, goats, asses, mules, and swine. The horses are both wild and tame, and the number of them, as well as that of the cattle, is immense. The inhabitants of the Pampas who superintend the herds are called *Gauchos*, an account of whom will be found in the article Buenos Ayres. Amongst the wild animals may be mentioned many species of large wild cats, the jaguar, cougar, chibi-guazo; puma, which may be said to represent the lion in the new world; different kinds of pole-cats, the zorillo, tajassu, tapir, armadillo, marten, wild dog, guanaco; chameleon, sometimes of an enormous size; monkey, deer, hare, rabbit, elk, rigua; many species of serpents, as the boa, rattlesnake, great water-serpent, viper, adder; crocodile, mosquito, wasp, ant, and so on. Amongst the birds of this country may be mentioned the white raven, the gold-coloured sparrow, the partridge, as large as a domestic fowl, the ostrich, pigeon, wild turkey, goose, and some others. There are seven kinds of bees, of which several produce honey that has a very considerable, and sometimes alarming effect, when taken in large quantities. Of fish there are sea-bream and gold-fish; crawfish, perch, shad; whales and seals, which yield train oil and fish-bone for exportation; sharks, eighteen thousand of their skins being annually exported; and turtles.

---

[2] Rough Notes taken during some rapid journeys across the Pampas and among the Andes. By Captain F. B. Head

Inhabitants. The inhabitants present the same national diversities here as in the other states of South America. Their number has been variously estimated at from half a million to nearly three millions; a sufficient proof of the uncertainty which prevails regarding the exact amount of the population of La Plata. In the Weimar Almanack for 1838 they are stated at 2,024,995, viz. Creoles of Spanish descent, 600,000; Mestizoes, 600,000; Indians, " fideles," 800,000; negroes, 25,000. Of aboriginal Indians there are numerous nations; but, as will be seen, the whole do not comprise a population at all commensurate with the varieties of distinct tribes. The Indians of the Pampas are said not to exceed eight or ten thousand souls.

La Plata consists of the following provinces, most of which have a capital city of the same name: Buenos Ayres, Cordova, Entre Rios, Corrientes, Catamarca, Mendoza or Cuyo, Rioja, Salta, Santiago del Estero, Santa Fe, San Juan, San Luis, Tucuman, and Tarija. Missiones is sometimes reckoned a province of La Plata, but it now belongs to Paraguay. Buenos Ayres, the capital, having already been described, we shall pass on to the other provinces.

Cordova. Cordova is bounded on the north by Santiago, on the south by the Indian territory and Buenos Ayres, on the east by Santa Fe, and on the west by San Luis. It extends about 110 leagues from north to south, and about the same distance from east to west. This is a fine province, the soil being rich and fertile, and well irrigated. It is pretty thickly set with trees, possesses excellent pasturage, and abounds in fine clover. Cordova, the capital of the province, is picturesquely situated in a deep valley, beside a river surrounded by mountains, in lat. 31. 15. south, long. 62. 40. west. It was founded in 1573, and became a place of considerable importance in the time of the Jesuits. In 1804 and 1810 attempts were made to render the river Tercero, which passes near Cordova, navigable from this point to its junction with the Parana; but the commerce of the country was too limited, labour too dear, and overland carriage too easy and cheap, to render this an eligible speculation, so that the attempt was abandoned. The population of the whole province has been estimated at 315,000.

Entre Rios. Entre Rios is situated between the two great rivers Parana and Uruguay, and is bounded on the north by the province of Corrientes, and on the south by Buenos Ayres. It possesses several peculiar advantages, and is one of the most fertile and pleasing provinces in the whole republic. Embraced on all sides but one by the two great rivers just named, it is easily accessible by shipping; and being thus insulated, it is protected from the incursions of the Indians. It is copiously irrigated, and the soil is distinguished for its fertility. Wood is abundant, but small in size. The pastures are extensive; but the wild cattle, which formerly abounded, are much reduced in number. There are two small towns in the province, each of which is dignified with the name of city; one is Badaja, opposite to Santa Fe, on the Parana, the other is Villa del Arroyo de la China, on the Uruguay. Farther south, and nearer to Buenos Ayres, there are two other towns, called respectively Gualeguay and Gualeguaychu, but they are still smaller than the two former. The great natural advantages of Entre Rios must ultimately raise it into a place of considerable importance. At present the population is computed at 105,000.

Corrientes. Corrientes is situated to the north of Entre Rios, and forms a continuation of that province, being also situated between the rivers Parana and Uruguay. On the north it is bounded by the state of Paraguay. It has an average breadth of about two hundred miles, and its length may exceed that, though the boundary line between it and Entre Rios has not been laid down with accuracy. The territory of Corrientes is intersected by several rivers, some of which are navigable for a considerable distance. Besides the celebrated lake Ybera, there are in the province numerous sheets of water, by which it is rendered one of the most fertile countries on the face of the globe. Corrientes, the capital, is admirably situated on the banks of the Parana, near its junction with the Paraguay. It is a very ancient city, but the population is inconsiderable. That of the whole province is estimated at 140,000.

Santa Fe. Santa Fe is situated between the river Parana and Cordova, which constitute its boundaries on the east and the west. On the south it is bounded by Buenos Ayres, and on the north by Santiago del Ostero. This fertile country is irrigated by numerous rivers, some of which are of considerable size. The chief employment of the inhabitants consists in the breeding of vicumras and horses, the skins of which animals are conveyed to Buenos Ayres. Santa Fe, the capital, is situated on the western part of the Parana, at about eighty leagues from Buenos Ayres, and has risen to importance by becoming a dépôt for goods on the river. The inhabitants of the town amount to about 4000, and those of the province to about 52,500.

San Luis. San Luis is bounded on the east by the provinces of Buenos Ayres and Santa Fe, on the west by Mendoza, on the south by the territory of the Pampas Indians, and on the north by Cordova. This province is reckoned about a hundred leagues in extent from north to south, and from fifty to sixty in breadth from east to west. The soil is uniformly productive, and the climate is salubrious, but the inhabitants are very indolent, and agriculture is not pursued to any extent. San Luis, the capital, is a very ancient town, and the only place of any importance in the journey between Buenos Ayres and Mendoza. It is situated in a fertile valley at the foot of a range of hills, and the entrance to it is through long lanes, having dead mud-walls on either side. The population of the town has been estimated at 15,000, and that of the province at 103,000.

Mendoza. Mendoza or Cuyo is a well-irrigated and fertile plain, bounded on the east by San Luis, on the west by the cordillera of the Andes, on the north by San Juan, and on the south by the Indian territory. From north to south it extends about a hundred and fifty leagues, and from east to west rather more than a hundred leagues. The inhabitants of this province are very industrious, and they raise wheat and maize for exportation. Their chief occupation, however, is the cultivation of vines and clover grass. A considerable quantity of wine is made, in which article an extensive trade is carried on, and also in brandy and dried fruits. One of the most productive branches of commerce is the transport of maté to the various provinces of the republic. Mendoza, the capital of the province, is a large town, situated in an extensive and well-cultivated plain at the foot of the Andes, between 32° and 33° of south latitude. Its most remarkable feature is a fine *alameda*, or public promenade, of great length and beauty. The town covers a considerable space of ground, as there is generally a vineyard, orchard, and garden attached to every house. The population of the city is estimated at 16,000. There are several other towns of some note, such as San Carlos, to the south, in the valley of Uco; Coricouto, to the east; and another in the same direction, eleven leagues from the city, called Los Barriales. Over the whole country there are numerous establishments and farms for breeding cattle and prosecuting various agricultural operations. The population of the entire province may be estimated at 103,335.

San Juan. San Juan is situated to the north of Mendoza, extending about a hundred and twenty leagues from north to south, and about the same distance from west to east, terminating, like Mendoza, at the foot of the Andes. The country is remarkably fertile, producing wheat, maize, olives, and vines, in abundance. The produce of the olive plantations is much esteemed in Buenos Ayres; but the natives direct their attention chiefly to the cultivation of the vine, which grows luxuriantly, and to the making of wines and brandies, which they export in large quantities as far as Potosi, Buenos Ayres, Santa Fe, and a great portion of the eastern side of the Rio de la Plata. The city of San Juan, situated in latitude 31. 15. south, and longitude 68. 35. west, was founded as early as 1560, and is consequently one of the most ancient places in the republic. It is now considered as the town which most closely follows Buenos Ayres in the march of social reform. The mines of gold and silver which were said to enrich this province have never yet been discovered. The population of the city of San Juan is estimated at 19,000, that of the whole province at 103,330.

Rioja. Rioja is situated to the north of San Juan, and also at the foot of the Andes. It is about one hundred and forty leagues in length, by nearly the same in breadth. Like the other provinces in this region, it is a mountainous table-land; and it shares with Mendoza and San Juan in the growth of vines, wheat, and maize. Rioja, the capital, is a small and unimportant city, situated in latitude 28. 30. south, and longitude 68. 35. west, two hundred and ninety leagues from Buenos Ayres. It contains about 3000 inhabitants; and the population of the entire province is reckoned at 87,500 souls.

Catamarca. Catamarca is a tract of country extending about one hundred leagues in length and nearly as much in breadth. It is situated near the foot of the Andes, under the twenty-eighth degree of south latitude, and is bounded by Tucuman and Salta on the north and east, by the Andes on the west, and by Rioja on the south. It consists of a mountainous table-land, but is noted for an extensive and fruitful valley, called the Valley of Catamarca. The temperature of this district is of the most genial description, and the country produces cotton of a very superior quality. The city of Catamarca is situated about sixty leagues south-east of Tucuman, in latitude 27. 45. south, and longitude 66. 0. west. It was founded more than a century and a half ago, and stands in the beautiful valley which bears its name. It contains about five thousand inhabitants. The other towns in this province are unimportant. The population of the whole province is estimated at 105,000 souls.

Tucuman. Tucuman, one of the most important and fertile provinces in the republic, is situated in the twenty-seventh degree of south latitude, having Salta on the north, and Santiago on the south and south-west, and extending fifty-eight leagues from north to south, and about fifty leagues from east to west. The rice which is called *de castilla* grows here in abundance, and is of a very superior quality. The other productions are, wheat, maize, ground pistachio-nuts, and tobacco, of which thousands of bales are exported to Cordova, San Luis, San Juan, Mendoza, and other cities. Fruits of various sorts are abundant; and potatoes here attain an enormous size. To the west of the city is a delightful mountain, of great height, from which sixteen rivers descend to fertilize and beautify the surrounding territory. These streams unite and form the river Santiago del Estero. Along all the lower parts of this mountain are immense clusters of trees, and amongst them many of bitter oranges. The city is surrounded by these woody tracts, which occupy a space of fifteen leagues. The trees sometimes attain an extraordinary size, and the timber is of the best quality used in America. Tucuman, the capital of the province, is a straggling city, situated in 26. 50. of south latitude, and 64. 35. of west longitude. The houses in general are of an inferior description; but the place is memorable from its having taken a distinguished part in the revolutionary struggle. The inhabitants, who amount to ten or twelve thousand, are described as hospitable, honourable in their dealings, of a mild disposition, and much inclined to labour. The other towns are Monteros, Suares, Chiquiligasta, Rio Chico, Francas, and Burroyaco, each of which constitutes a large parish, at the same time that it contains minor parishes. The population of the whole province is estimated at 140,000 souls.

Salta. Salta is situated to the north of Tucuman, and is of considerable extent. Its western part belongs to the great range of the Cordilleras, and is rich in metals. Here are found gold and silver, copper, iron of various qualities, sulphur, alum, vitriol; and there are also indications of the existence of tin and quicksilver. Many branches of mountains, off-shoots from the colossal chain of the Andes, extend into the province, from which proceed pleasant and beautiful valleys, intersected by numerous streams which irrigate and fertilize the country. In one of the intervals between the low collateral branches of the Andes is situated the capital. To the eastward of the city the country becomes flat, and continues so to the borders of the Bermijo and Parana. The city of Salta, the capital of the province, is situated in lat. 24. 15. south, and long. 64. 0. west, on the great road leading from Buenos Ayres to Lima by the way of Potosi. It was founded in 1582, and has long been a place of some consideration in this thinly-peopled region. The population amounts to about 9000 souls. The other towns in the province are Caldeva, Rosania de la Frontera, Rosario de Serrillos, Chicoana, Atua, and a few small villages. The population of the whole province is estimated at 140,000 souls.

Santiago. Santiago del Estero is situated between Tucuman and Cordova, being south of the former and north of the latter. It is of great extent in all directions, and is one of the most fertile of these provinces. Agriculture is the chief occupation of the inhabitants of Santiago. Wheat produces eighty fold, and it requires little or no aid from art to raise this heavy crop. All kinds of grain may here be brought to perfection, yet the inhabitants are slow to avail themselves of the advantages presented by nature. The city of Santiago, situated on the road to Bolivia through Cordova, in 27. 55. south latitude, and 63. 20. west longitude, is thinly peopled, and of little importance. The river Santiago runs close past it in its course to the great lake by which its waters are absorbed. The population of the whole province is estimated at 210,000 souls. This province, along with those of Tucuman and Cordova, are all bounded on the east by that vast territory called Grand Chaco, extending hence to the river Parana. It is the native country of the Abipones, and once contained 2,000,000 of aboriginal inhabitants. The Spaniards formed several establishments here, but their cruelties drew down upon them the vengeance of the Indians, who effected their extirpation. The inhabitants of the Grand Chaco, although now very much reduced in number, still retain their independence.

Tarija. Tarija is the most northerly province in the Argentine Republic, and consequently borders upon Bolivia, to which it in reality belongs, although politically it forms one of the provinces of the Rio de la Plata. It consists of a succession of charming valleys, with a delightful climate and a fruitful soil. Corn, maize, the yerba-maté of Paraguay, the cocoa, flax, and every necessary of life, are produced here in the greatest abundance. No part of America indeed seems to be superior to this district of Tarija; and the reason why it is so little known is, that, possessing no mineral treasures, and being inhabited merely by an agricultural people, the Spanish authorities never deemed it worthy of the slightest attention. To the south-east of this province lies Jujuy, which, in the event of Tarija being permanently united with Bolivia, will be erected into a province of the Argentine Republic; indeed some recent writers reckon it such already. It is of much the same character as Tarija, having a very prolific soil, and producing abundance of similar productions. There are some mines of gold in this territory, but they have not been worked to advantage. The city of Jujuy lies on the road from Buenos Ayres to Upper Peru, and is a very old place. The whole district contains from 50,000 to 60,000 inhabitants.

Executive power.

Don Juan de Rosas was in 1835 appointed dictator of the republic for five years. There are four principal ministers, one for each of the foreign, home, finance, and war departments. The state religion is the Roman Catholic, which is under the direction of four bishops. The Jesuits, who nearly three fourths of a century ago were expelled from this and other parts of South America, have been allowed to return.

The commerce of the country, the state of education, and its moral aspect generally, will be found described in the article Buenos Ayres.

According to official accounts from Buenos Ayres, the finances stood thus on the 7th of April 1836: Income, 11,727,446 dollars; expenditure, 8,439,165 dollars; surplus, 3,288,281 dollars. On account of the public debt, 7,747,000 dollars fall to be deducted, thereby giving rise to a deficiency, which was covered by the sale of 1200 leagues of the states land. It appears, however, that these accounts are little to be depended upon; for, according to the budget for 1837, the income was 12,000,000 dollars, and the expenditure 18,315,124 dollars, thus making a deficit of more than 6,000,000 of dollars. To cover these deficiencies, and wipe out the accumulated debt, it is proposed to obtain a native loan of 17,000,000 dollars. Altogether, the accumulated debt of the Argentine Republic amounts to 42,000,000 dollars.

Constitution.

The constitution of this federal republic has not yet been completely organized. The head state, the seat of the congress or legislative assembly, is Buenos Ayres. The number of senators amounts to forty-eight, and that of deputies to eighty-eight. The states are all at liberty to manage their own affairs, each having a governor, with subordinate functionaries. In all of them the principle of democracy is recognised, but practically it is more acted upon in some states than in others. Where the governor has great influence, either from his wealth or from other circumstances, he is frequently found to evince a distaste for legislative control. Occasionally, indeed, they openly avow themselves absolute; and as Buenos Ayres can exercise but a feeble authority over those provinces which are situated far in the interior, they are not always called to a strict account of their stewardship.

In conclusion, it may be observed, that the union of the provinces forming this republic is far from being perfect. They exercise too much individual independence, and are too jealous of each other, and of the capital in particular, heartily to entertain common views for the general good. They are as yet but weakly cemented together, and a long period will elapse before they are fused into one homogeneous mass. This is no doubt in part owing to their being spread over a vast extent of country; but, when communication between distant parts becomes more easy and frequent, which it will be when the rivers are rendered properly navigable, so as to facilitate commerce, then a more complete amalgamation of the whole may confidently be anticipated. (R. R. R.)

PLATÆÆ, in *Ancient Geography*, the name of a strong town in Bœotia, which from its situation was exposed to the north wind. It was burned to the ground by Xerxes; and it was famous for the defeat of Mardonius the Persian general, as also for the signal victory of the Lacedæmonians and other Greeks under Pausanias the Lacedæmonian, and Aristides an Athenian general, in memory of which the Greeks erected a temple to Jupiter Eleutherius, and instituted games which they called Eleutheria. Platææ stood at the foot of Mount Cithæron, on the road to Athens and Megara, and on the confines of Attica and Megaris.

PLATFORM, in the military art, an elevation of earth, sometimes covered with planks of wood, upon which cannon are placed to fire on the enemy. On the ramparts there is always a platform, where the cannon are mounted. It is made by heaping up earth upon the rampart, or by an arrangement of madriers, rising insensibly, for the cannon to roll on, either in a casemate, or, on attack, in the outworks. All practitioners are agreed that no shot can be depended on unless the piece can be placed upon a solid platform; for if the platform shakes with the first impulse of the powder, the piece must likewise shake, which will alter its direction, and render the shot uncertain.

Platform, in *Architecture*, is a row of beams which support the timber-work of a roof, and lie on the top of a wall where the entablature ought to be raised.

This term is also used for a kind of terrace or broad smooth open walk at the top of a building, whence a fair prospect may be obtained of the adjacent country. Hence an edifice is said to be covered with a platform when it is flat on the top, and has no ridge. Most of the oriental buildings are covered in this manner, as were all those of the ancients.

PLATINA is a metallic substance, the name of which has an allusion to its colour. It is a diminutive of *plata*, and signifies little silver. From its great specific gravity, and other resemblances which it has to gold, it has been called *or blanc*, or white gold; from its refractory nature, *diabolus metallorum*; and from some doubts entertained of its character as a metal, *juan blanco*, white jack, white rogue, or white mock metal. It has also received the appellation of the *eighth metal*; and, probably from some district which affords it, has been called *platina del Pinto*.

PLATING is the art of covering baser metals with a thin plate of silver, either for use or for ornament. It is said to have been invented by a spur-maker, not for show, but for real utility. Till then the more elegant spurs in common use were made of solid silver, and, from the flexibility of that metal, they were liable to be bent into inconvenient forms by the slightest accident. To remedy this defect, a workman at Birmingham contrived to make the branches of a pair of spurs hollow, and to fill that hollow with a slender rod of steel or iron. Finding this a great improvement, and being desirous to add cheapness to utility, he continued to make the hollow larger, and of course the iron thicker and thicker, till at last he discovered the means of coating an iron spur with silver in such a manner as to make it equally elegant with those which were made wholly of that metal. The invention was quickly applied to other purposes; and to numberless utensils which were formerly made of brass or iron are now given the strength of these metals, and the elegance of silver, for a small additional expense.

The silver plate is generally made to adhere to the baser metal by means of solder, which is of two kinds; the soft and the hard, or the tin and silver solders. The former of these consists of tin alone, the latter generally of three parts of silver and one of brass. When a buckle, for instance, is to be plated by means of the soft solder, the ring, before it is bent, is first tinned, and then the silver-plate is gently hammered upon it, the hammer employed being always covered with a piece of cloth. The silver now forms, as it were, a mould to the ring, and whatever of it is not intended to be used is cut off. This mould is fastened to the ring of the buckle by two or three cramps of small iron wire; after which the buckle, with the plated side undermost, is laid upon a plate of iron sufficiently hot to melt the tin, but not the silver. The buckle is then covered with powdered resin, or anointed with turpentine; and, lest there should be a deficiency of tin, a small portion of rolled tin is likewise melted on it. The buckle is now taken off with a tongs, and commonly laid on a bed of sand, where the plate and the ring, whilst the solder is yet in a state of fusion, are more closely compressed by a smart stroke with a block of wood. The buckle is afterwards bent and finished. Sometimes the melted tin is poured into the silver mould, which has been previously rubbed over with some flux. The buckle ring is then put amongst the melted tin, and the plating finished. This is called by the workmen *filling up*.

But when the hard solder is employed, the process is in many respects different. Before the plate is fitted to the iron or other metal, it is rubbed over with a solution of borax. Stripes of silver are placed along the joinings of the plate, and instead of two or three cramps, as in the former case, the whole is wrapped round with small wire; the solder and joinings are again rubbed with the borax, and the whole is put into a charcoal fire till the solder be in fusion. When taken out, the wire is instantly removed, the plate is cleaned by the application of some acid, and afterwards made smooth by the strokes of a hammer.

Metal plating is when a bar of silver and another of copper are taken of at least one equal side. The equal sides are made smooth, and the two bars fastened together by wire wrapped round them. These bars are then sweated in a charcoal fire, and after sweating, they adhere as closely together as if they were soldered. After this they are flattened into a plate between two rollers, when the copper appears on one side and the silver on the other. This sort of plate is named *plated metal*.

French plating is when silver-leaf is burnished on a piece of metal in a certain degree of heat. When silver is dissolved in aquafortis, and precipitated upon another metal, the process is called *silvering*.

PLATO.

The birth of Plato is nearly coincident with that great epoch of Grecian history, the commencement of the Peloponnesian war. In the first year of that war, the Athenians, having ejected the unhappy people of Ægina, apportioned the island amongst colonists from themselves.[1] Amongst these Athenian occupants were Aristo, and Perictione. or Potona, as she is also called, the father and mother of Plato. Their residence, however, in the island was not permanent nor even long, as the intrusive colony was in its turn ejected by the Lacedæmonians, on which occasion his parents returned to Athens.[2] It was during this interval, and in the year 429 B. C., that the philosopher was born.[3]

From these circumstances, it has been commonly supposed that Plato was born in Ægina. They are not, however, sufficient to establish such a conclusion. For a colonization of the kind here described did not necessarily imply residence on the part of those persons to whom the lands were allotted.[4] Nor is the fact of the recovery of the island by the Lacedæmonians from the hands of the Athenians, mentioned by the contemporary historian. Ægina was still in the occupation of the Athenians in the fifth year of the Peloponnesian war;[5] and in the eighth year of the war we find that the poor exiles, who had meanwhile obtained a refuge at Thyrea, were there cruelly exterminated by the Athenians.[6] On the whole, it seems more probable, from the constant designation of Plato as "the Athenian," without any other addition, though this alone, it must be allowed, is not decisive of the fact, that Athens itself may claim the honour of having been his birthplace.

It is remarkable that his proper name was not that which his fame has immortalized, but Aristocles, after his paternal grandfather.[7] The name of Plato is said to have been given to him by the person who was his master in the exercises of the gymnasium, as characteristic of his athletic frame in his youth.[8] In this way, being familiarly applied to him, it gradually prevailed, to the entire disuse of his family name.

The philosopher was connected by descent with the ancient worthies of Athens; on his mother's side with Solon, and on his father's with the patriot king Codrus.[9] And thus, according to the notions of nobility prevalent amongst the Greeks,[10] he could trace up the honours of his parentage to a divine founder, in the person of the god Neptune.

A circumstance is related of his infancy, which, though obviously fabulous, cannot properly be omitted in his biography, as a pleasing and appropriate tribute of the imaginative genius of the Greeks to their poet-philosopher. Whilst he was sleeping when a babe, on Mount Hymettus, in a bower of myrtles, during the performance of a sacrifice by his parents to the muses and nymphs, bees, it is said, lighted on him and dropped honey on his lips, thus giving an evident augury of that peculiar sweetness of style by which his eloquence would be distinguished.[11]

For the same reason, a similar fancy, which has thrown a poetical ornament over the account of his first devotion to philosophy, must not be passed over in silence. Socrates, it is related, was apprized beforehand, in a dream, of the first visit of the gifted pupil, who was destined to carry philosophy forth on the wings of his genius to its boldest flights. Socrates was telling his dream to some persons around him, how he seemed to see a young swan coming from an altar in the grove of Academus, and first nestling in his bosom, then soaring up on high, and singing sweetly as it rose in the air, when Aristo presented himself, leading his son Plato, whom he committed to the instruction of the sage. Socrates, it is added, struck by the coincidence, immediately recognized the fulfilment of his dream, and welcomed Plato as the young swan from the altar, represented to him in the vision.

[7] Aristocles was also a Spartan name, being the name of the brother of the king Pleistoanax. Thucyd. v. 17.

[8] As derived from πλατυς, *broad*. Laertius gives this explanation, which Seneca also adopts (*Epist.* lviii. 27), but says others interpreted the name as denoting a broad forehead; others, as characteristic of his style of eloquence.

[9] His family also is shewn to have been of rank, from its connection with some of "the Thirty," called "the Thirty Tyrants," established at Athens by the Lacedæmonians. See Plat. *Ep.* vii.

[10] See Herodot. *Euterp.* 143.

[11] Cicero, *De Divin.* i. 36.

The accounts of his early education, to which we should naturally have looked with great interest, are extremely meagre. We only know by general notices that he passed through the usual course of education adopted amongst the higher classes of the Greeks. That education was directed to the cultivation at once of the powers of the mind and of the body, under the two great divisions of literature and gymnastics. The youth was delivered to the charge of the grammarian, the teacher of music, and the trainer. From the grammarian he learned the art of reading and writing his own language, and a knowledge of its authors, especially its poets; from the teacher of music, skill in performing on the lyre and the flute, together with the principles of the science of music; from the trainer he acquired strength and expertness in the several exercises of wrestling, and boxing, and running, by which it was intended not only to mature the powers of the body, but to qualify the youth for attaining eminence at the public games. These were the schoolmasters of the accomplished Athenian, and with these he was occupied until he had reached about his twentieth year. Accordingly, the names have been transmitted to us of those who discharged these offices for Plato; of Dionysius, as the grammarian under whom he learned the elements of that command over his own language, and its literary resources, which his matured eloquence so richly displayed; of Draco of Athens, and Metellus of Agrigentum, as his masters in music; and of Aristo the Argive, as his master in gymnastics. It is added that he also studied painting; but the name has not been given of any individual who acted as his preceptor in the art.

In evidence of his great proficiency in these early studies, it has been stated, that he gave specimens of his genius in every department of poetical composition; that in epic poetry he laboured after the highest excellence, and only abandoned the attempt on comparing his efforts with the poems of Homer, and despairing of reaching so high a standard; that in dramatic poetry, he had prepared a tetralogy, the four plays usually required of an author in order to competing for the prize at the festival of Bacchus, but changed his purpose only the day before the exhibition, in consequence of impressions received from Socrates. And even in gymnastics excellence has been claimed for him; since it has been asserted that he actually entered the lists at the Isthmian games.

Whatever credit we may give to these particulars, there can be no doubt, that so inquisitive a mind as that of Plato, and so resolute a spirit in the prosecution of its undertakings, received the full benefit of this preliminary culture; and that he was thus amply prepared for entering on the severer discipline of those pursuits which engaged him when he became a hearer of Socrates.

This preliminary education, in fact, was very imperfect as a discipline of the mind. It gave the youth a forwardness and fluency of knowledge, so that he was fain to fancy himself, when he had scarcely attained manhood, equal to undertake affairs of state, and to serve the highest offices of the government. But it did not form his mind or character. He had yet to learn the nature of man; to study the principles of ethics and politics. This task of instruction devolved on the sophist or the philosopher (as the same person was at first indifferently called), into whose hands the Greek youth was now delivered.

Plato, accordingly, at the age of twenty years, began to be a regular attendant on the lessons of Socrates. The reputation of Socrates as a teacher in this higher walk of education, now eclipsed that of all other professors of philosophy. He had at once exposed the incompetence of the sophists who preceded him, and superseded them in their office. Plato would be conducted to him by his father, as the account states he was, very much in the way which is depicted under caricature by the comic poet,[1] as to the most distinguished master of the day, to be qualified for taking on him those public duties to which every citizen of Athens might be called; to enable him to distinguish himself in counsel and argument, and obtain influence and importance in society. From the numbers that resorted to Socrates, as well as to the sophists before him, it is plain that, to obtain instruction in philosophy for its own sake, or to become philosophers themselves, was not the object with which he was sought by the generality. Here and there the spark fell on a kindred genius, and lighted up a flame of philosophy in the breast of a disciple. Thus from the school of Socrates came the founders of several other schools; and, on the whole, a greater impulse was given by his teaching to the study of philosophy than had ever been felt before in Greece. Still, as Socrates himself did not profess to teach his hearers wisdom, so neither did they in general come to him as learners of wisdom, or as actuated by the pure love of wisdom, but to acquire practical information which their previous studies had not given them. We may imagine such a disciple as Plato first presenting himself amongst the multitude of hearers; how he would be struck by the first observation of the extraordinary manner of Socrates, especially at finding the very person to whom he came to be taught professing that "he knew nothing;" and that he was only wiser than other men on this account, that, whilst others knew not and presumed they knew, he neither knew nor presumed that he knew. The interest of such a mind as Plato's could not but be powerfully called forth by so strange an avowal on the part of a man whom he had been led to look up to as the wisest of men. To him it must naturally have prompted the questions, what philosophy might be; what the nature and condition of man; what the criteria of truth and falsehood; and thus have firmly laid hold of those tendencies to speculation which we see fully developed in the mature fruits of his genius. Again and again he is present at the searching investigations carried on in the discussions of which Socrates is the leader; soon he is himself interrogated by Socrates; and we cannot doubt that he is thenceforward irrevocably become, not the disciple of Socrates only, but the disciple and votary of philosophy.

That Plato was thus won over to philosophy from an early period of his life, is evident from the statement of Aristotle respecting him, that "from his youth he had been conversant with Cratylus, and the opinions of Heraclitus,"[2] and from the indications in two at least of his dialogues (and these supposed to be the earliest in the date of their composition, as written indeed during the lifetime of Socrates), the *Phædrus* and the *Lysis*, of his early acquaintance with Pythagorean notions.

There seems, too, but little room to doubt that he had begun at the same time to study the doctrines of the Ionic school under Hermogenes, as well as those of Parmenides and Zeno. For what he puts into the mouth of Socrates in the *Phædo*[3] respecting Anaxagoras, is probably (as Socrates himself was known to have had a strong aversion to physical science) the expression of his own disappointment and dissatisfaction at the outset of his studies, in the conclusions of the school, of which Anaxagoras was then the chief authority. Of Parmenides, again, he more than once speaks in terms of enthusiasm, as of a name with which he had very early associations of reverence;[1] here, as in the instance of Anaxagoras, we are disposed to think, depicting, in the person of Socrates, a portion of the history of his own mind.

---

[1] Aristoph. *Nubes.*

[2] Aristot. *Metaph.* i. 3.

[3] *Phæd.* pp. 220–225, ed. Bip.

Judging indeed from the tenor of his writings, we should conclude that his curiosity was excited, from a very early period, to explore the whole field of philosophy; and that, so far from resting on what he learned from Socrates himself, he applied the lessons of Socrates to the extending and perfecting those researches which he was carrying on at the same time, by means of books, or oral instruction from others.[2] Socrates was to him the interpreter, and commentator, and critic, of the various philosophical studies in which he was engaged. For this is the view which he has given us of Socrates in his Dialogues. Socrates there seldom or never appears as a didactic expounder of truth. He is presented as the critic of opinions and doctrines and systems, and the judge to whom everything is to be submitted for approval, or rejection, or modification, as the case may be.

Indeed, so exuberant and energetic a mind could not have been satisfied with being simply a learner in any school. It would eagerly seek the means of comparing system with system, and of examining into points of agreement or disagreement in the theories proposed. The doubts raised by Socrates, the hints thrown out by him, the conclusions to which he pointed, but which he yet left unconcluded, would to such a mind seem as so many points of departure for its own excursions. They naturally suggest that much more must be done than merely to take up what has been said by Socrates, in order to work out, or even rightly to conceive, what had fallen from his lips. For the conversations of Socrates were not framed to convey positive instruction, so much as to set the mind of the hearer a-thinking, and to provoke further inquiry. In the living pictures of them which Plato has drawn, they leave off just at the point where we expect the teacher would proceed to speak out more distinctly, and tell us precisely what his view of the subject is. If these pictures represent (as we may reasonably believe they do) the impressions received by Plato from the conversations of Socrates, what stimulants to inquiry must he have felt in the several particulars which he has so forcibly touched,—in the mingled lights and shadows of the scenes in which the great master occupies the foreground. Well therefore may we conceive that, at the time when he enjoyed the guidance, and control, and encouragement of Socrates, he was laying a broad foundation of erudition for that vast and richly-ornamented fabric of philosophy which the existing monuments of his genius exhibit.

From Socrates himself this demand of the inquisitive hearer could evidently not be supplied. Socrates was deficient in erudition properly so called. He had studied men rather than books. His wisdom consisted of deep and extensive observation accurately generalized, drawn from passing things, and capable accordingly of ready application to the same course of things; forcibly convincing his hearers by the point and propriety with which it met each occasion, and giving experimental proof of its soundness and truth. Erudition, accordingly, was to be sought elsewhere; and Plato therefore supplied this need from other sources, infusing it into, and blending it with his own speculations, whilst the Socratic spirit mellows the whole mass, and gives unity to the composition.

The death of Socrates, his tears over which Plato has recorded in that affectionate and interesting memorial of his master's truth and dignity, the Dialogue of the *Phædo*, naturally excited alarms for their own safety amongst those who were conspicuous disciples of the martyred sage. They saw, by the violent extremity to which the spirit of intolerance had proceeded, unchecked by any feeling of humanity or regard for truth, that the wisdom, and gentleness, and benevolence of an enlightened philosophy were no securities against the deadly hatred of bigotry. They found that the malignant tongue of priestcraft could stoop to employ any instrument, however mean, for the accomplishment of its purpose; that it could instigate the actor on the scene of civil affairs to do its work of sycophancy, whilst the prompter of the mischief, lurking in ambuscade, wore the mask of concern for the public good, and even arrogated the merit of sanctity, and truth, and tenderness. Persecution has ever been the same. Its essential features are vices of the human heart, not of any particular system of religion. We find it, accordingly, in several recorded instances in the heathen world, displaying itself very nearly as in the dark times of anti-Christian corruption. Athens itself had already furnished examples of its untiring and sure vengeance. In particular, the case of Anaxagoras had been a striking illustration. When not even the power and the eloquence of Pericles could save Anaxagoras from a prison, and expulsion from Athens, on account of his physical speculations; the very philosopher whose system of physics raised an insuperable barrier against atheism, by demonstrating the supremacy of mind; it was but too evident that there was a mysterious agency working in the heart of society, like secret fires in the depths of the earth, capable of awing and paralyzing every other power.

A more recent experience of the same truth, within the memory of the youngest disciple of Socrates, was in the dark proceedings consequent on the mutilation of the Hermæ, the rude images of Mercury erected in the vestibules of private houses as well as in the sacred places of Athens, and on the discovery of the profanation of the Eleusinian mysteries by the mock representation of them in private houses.[3] The secret information on which those proceedings were carried on; the indifference shewn at the period of alarm to everything else, even on an occasion of great public interest, but the vindication of the popular superstition; the effect which the charge of being implicated in these outrages had in checking the career of Alcibiades at the moment of his triumph over his political opponents; all shewed, that it was a vain hope to resist the secret arbiters of public opinion on questions of religion. Then came the fearful consummation of this vengeance in the death of Socrates by the poisoned cup; leaving no doubt in the minds of any, that they who would follow his example in boldly and honestly inquiring into current opinions, and declaring their convictions of the truth on matters affecting the conduct of men, must either prepare themselves for exile (which alone was a great punishment in the ancient world),[4] or drink the hemlock.

---

[1] Μελισσον μεν και τους ἀλλους οἱ ἑν ἑστως λεγουσι το παν, αἰσχυνομενος μη φορτικῶς σκωπτωμεν, ἧττον αἰσχυνομαι, ἢ ἑνα ὀντα Παρμενιδην. Παρμενιδης δε μοι φαινεται το του Ὁμηρου, αἰδοιος τε μοι εἶναι ἁμα δεινος τε· συμπροσεμιξα γαρ δη τῷ ἀνδρι, πανυ νεος, πανυ πρεσβυτῃ· και μοι ἐφανη βαθος τι ἐχειν πανταπασι γενναῖον. (*Theætet.* pp. 137, 138. *Parmenid.* p. 72.)

[2] This evident early devotion of Plato to the pursuit of his whole life, argues the mere calumny of that statement which represents him to have at first sought his fortune by the profession of arms. The calumny is a current one, which has been applied to other philosophers. He has also been absurdly represented as present at the battles of Tanagra and Delium, when he was, in truth, a mere child.

[3] The performance of religious rites in private houses is forbidden in Plato's Dialogue on Laws, x. p. 117.

[4] Cicero says of exile, endeavouring to reconcile the feelings to it, "jam vero exilium, si rerum naturam, non *ignominiam nominis* quærimus, quantum demum a perpetua peregrinatione differt." (*Tuscul. Quæst.* v. 37.)

Socrates himself had the courage to take the latter part of the alternative. To him it was the natural termination of that energetic course which he had from the first adopted. He would have unsaid all his teaching; he would have practically recanted the strong language in which he had, through all his life, been discoursing of the worthlessness of the body and of the present life, and of the immortality and perfection of the soul. His philosophy kept him immured in his prison, and riveted the fetters on his limbs, far more than the condemnation of his judges or the hammer of the jailor. For, as he says of himself in the words in which Plato has naturally expressed his sentiments in the prison, his "sinews and bones would long ago have been at Megara or in Bœotia," had he not thought it "best," and firmly fixed his resolution, to abide the issue there.[1]

But this was not the case with the hearers of Socrates. They were not, like him, placed in a commanding post, from which they could not retreat without being stigmatized as deserters of their profession, and betrayers of the truth. They might with honour and propriety consult for their safety. Whilst, therefore, as is probable, the bulk of those who had attended on the teaching of Socrates simply withdrew from public notice, and retired to their homes at Athens or elsewhere, the principal disciples of the school, —those who were most known as followers and admirers of Socrates,—left Athens, and sought an asylum for themselves and for philosophy at Megara.

Amongst those whom Socrates drew around him were several individuals of mature age, already trained in some sect of philosophy, and eminent in their own walk of science, yet desirous of availing themselves of the far-famed wisdom of the sage of Athens. Of this class was the philosopher Euclid, from whom the Megaric school derives its existence and celebrity.[2] As a disciple he belonged to the Eleatic school, and, trained by Zeno, the great master of dialectic before him, had made that science his especial study. He had shewn a singular zeal in attending on the lessons of Socrates; for he continued to go to Athens for that purpose, even when the obnoxious decree of exclusion against Megareans, on pain of death, had been passed by the Athenians; setting out at night-fall on a journey of more than twenty miles from Megara to Athens, and assuming the disguise of female attire that he might pass unnoticed.[3] His conduct on the occasion of the dispersion of the school of Socrates corresponded with this zeal. He received the members of the school with open arms, and gave them a home with him at Megara. There, for a time at least, they gathered themselves, in shelter from the storm which had driven them from Athens. But the school, in fact, was broken up. It had subsisted and been held together by the personal influence of Socrates himself, and with him its principle of vitality, as a body, was gone. He had not laboured to establish a sect or a theory; and he left therefore no particular rallying point, or symbol of union, around which a party might be formed. He was himself the symbol of union to his disciples; bringing together around him the professors and disciples of every different sect. There was yet to arise out of his society one who, richly imbued with his doctrine and method, should rekindle the extinct school with his own spirit, and bid it live again in its genuine offspring; and that individual was Plato. But the times were not yet ripe for this.

In the mean time Plato was destined to spend several years in journeying from place to place, at a distance from the past and the future scene of his philosophical labours. These were doubtless years of great importance to him, for the perfect formation of the peculiar character of his philosophy. In the course of them, we find him visiting Megara, Cyrene, the Greek settlements on the coast of Italy, Sicily, Egypt, "exploring (as Cicero says of him in oratorical language) the remotest lands,"[4] after the manner of Solon and Pythagoras, and other wise men before him, who had enlarged their minds by contemplations pursued in foreign travel. Thus did he singularly combine in his studies the more ancient with the Socratic mode of philosophizing. The method of Socrates was exclusively domestic. He studied mankind within a small compass (the circle of Athens itself), only with a more accurate and searching eye than any one had ever done before him; and therefore drew sound general conclusions from his observations within that range of view. He evidently judged it better thus to restrict the attention, and require men to investigate closely what lay before them, than to encourage them to indulge the prevailing habit of more diffusive and vague observation. This is told us in other words by Plato himself, where he introduces Socrates as a stranger even to the beautiful scenery in the immediate neighbourhood of Athens, and as one who appeared never to have been out of the walls of the city; and as owning that, in his fondness for study, he was content to learn of the men in the city, who could teach him what the fields and the trees could not.[5] But this method, good as a foundation, and necessary as a corrective of desultory and superficial habits of thought and study, was not sufficient for the requirements of Plato's mind. He observes in one of his works that there is much to be gained from contemplation rightly directed in foreign travel both by land and sea; that we are not only to look to our own country for examples, but seek in the world at large for specimens of the highest order of men, which, though rare, might, from time to time, be found under every form of government; and that no perfect civilization can be attained without this means of observation and improvement.[6] He describes, in fact, the course which he had himself pursued, and the benefit which he had found resulting from it.

Having sojourned for a time at Megara, together with the other disciples of Socrates, and probably there, with the assistance of Euclid, increased his acquaintance with the writings of Parmenides and Zeno, as well as studied more intimately the dialectic of their school, he appears to have proceeded to Cyrene. Cyrene was the home, not only of Aristippus, to whose school it afterwards gave its name; but of the venerable Theodorus, the most eminent geometrician of his day. Theodorus had been occasionally a resident at Athens, and an attendant on the teaching of Socrates, whilst he was himself resorted to by the Athenian youth for instruction in the science of geometry.[7] Plato no doubt had been amongst those who had thus availed himself of the presence of Theodorus at Athens. His predilection for mathematical studies is conspicuous throughout his writings. His skill in geometry, in particular, requires no other evidence than the interesting fact of his ready solution, in that infant state of the science, of the oracular problem which required the doubling of the cubic altar at Delos.[8] He has described Theodorus as present at Athens at the time when the prosecution was instituted against Socrates.[1] He now went to Cyrene, probably with the view of following up that course of geometrical study which had been so abruptly terminated; whilst he regained also the society of a friend for whom he evidently felt respect and admiration.[2]

[8] Plutarch. *De Socrat. Genio*, p. 288, tom. 8, Reiske. The inscription said to have been over the portal of the Academia, "Let no one enter who is not a geometrician," seems to belong rather to Pythagoras, or perhaps was imitated from the Pythagoreans.

The course of his travels conducted him to the Greek settlements on the coast of Italy and Sicily, where the colleges of the Pythagoreans were established. It may readily be imagined with what eager curiosity Plato undertook this voyage, what delight he promised himself in seeing the place itself where Pythagoras had taught, and in personal conference with the living successors of the mystic sage, and in obtaining a greater insight into the doctrines of a school which had such charms for him. He had much to observe also in the peculiar discipline by which the Pythagoreans were formed into a distinct fraternity amongst themselves. Greece Proper had nothing to exhibit like this. For though the different sects of philosophy were distinguished there by the names of founders and places, they were not held together by any rules of discipline. But the Pythagoreans at Tarentum, Crotona, and elsewhere in Magna Græcia, had incorporated themselves into synedria, or colleges; each individual giving his property in common, and regarding the bond of connection with his brethren of the sect as closer than the ties of kindred.[3] Associations of this kind must have appeared, at the first, as anomalies even to the philosophical Athenian, accustomed as he was to regard the free intercourse of social life as indispensable to his very existence.

It has been said that Plato was admitted to the secret discipline of the Pythagoreans. Probably he was only received by them with great cordiality, and had access to writings and information respecting their doctrines, which would have been denied to one, who came less recommended to them by the sincere enthusiasm of philosophy, and approximation to their views. There are no traces certainly in his writings, or elsewhere, of his having been a professed Pythagorean; although he undoubtedly was greatly captivated by the Pythagorean doctrines, and has introduced them largely into his own speculations.

Archytas, the greatest name of the Pythagorean school after that of Pythagoras himself, was then flourishing at Tarentum. It must have been an interesting occasion, when there were assembled together at Tarentum, as Cicero relates,[4] Pontius the Samnite, the father of that Pontius who defeated the Roman consul at the Fauces Caudinæ; Archytas the Pythagorean, discoursing against pleasure; and Plato the Athenian. The very place where they met,—a point of contact between the old empires of the world, and the rising power destined to break them in pieces,—in itself adds to the interest. Then the characters of the two philosophers who thus met, further arrest our attention:—Archytas, the representative of the old traditionary theological systems now moulded into a scheme of philosophy and a discipline of life; and Plato, the accomplished artist, who was soon to take up the scheme of philosophy where the Pythagoreans left it, and consecrate it by the inspirations of his own genius to an eternal empire on the throne of literature:—Archytas, nurtured in the reserve and mysticism of the Pythagorean discipline; Plato, formed to busy and importunate discussion by the ever-colloquial Socrates,—two philosophers so contrasted with each other in many respects, and yet so concordant in their love of ancient wisdom and indefatigable research after truth.

From the Pythagoreans Plato proceeded to Egypt to converse with the priests of that ancient land, from which Greece had derived her original civilization and science. Since the settlement of the Greek colony in Egypt by Psammetichus,[5] there had existed a regular channel of intercourse between Greece and Egypt, and accurate means of information to the Greeks respecting Egypt. The history of Herodotus must in itself have awakened the curiosity of those who had any taste for such inquiries, to know still more of a people from whom Greece had already learned so much, and from whom evidently so much was to be learned; and must have stimulated them to avail themselves of the existing facilities of gratifying that taste. To Plato, indeed, if we take the testimony of Herodotus, that the Greeks, though they had endeavoured to appropriate the discovery, derived the doctrine of the immortality of the soul from the Egyptians (who were the first, he thinks, to teach the doctrine, accompanied with that of transmigration),[6] a visit to Egypt must have been most attractive. Herodotus has given us an engaging view of the impression which such a visit produced on his mind. What an animated picture might the still more philosophical mind of Plato have presented, of the result of his conversation with the priests of Egypt. Though we may not credit the account of his having had the mysterious wisdom of the Hermetic Columns unfolded to him by the priests, and of his being instructed in magic,[7] on this occasion; we have intimations of the treasures which he collected in Egypt scattered through his writings, and, so far, some evidence that this visit was not without its influence on the character of his philosophy.

Indeed it has been further asserted, that, whilst in Egypt, he had access to an existing Greek version of the Old Testament, and that to this circumstance we must attribute that purer and more elevated theology which his works exhibit, in comparison with those of other heathen philosophers. A strange oversight in chronology has also attributed to him a personal intercourse with the prophet Jeremiah.[8] These statements are obviously mere suppositions, by which Christians, over-zealous for Plato's philosophy, vindicated their admiration of it, whilst they asserted also the originality and supremacy of Scripture truth. At the same time, it is indisputable that Judaism diffused much religious and moral truth beyond its own pale; and that not only Plato, but the Egyptian priests, his instructors, unconsciously derived much from the inspired sources, in collecting, under the form of fable, or allegory, or maxim, portions of truth which the sacred oracles had scattered around them in their transmission.[9]

Having traversed Egypt, where he is said to have assumed the disguise of an olive-merchant, in order to journey more securely in a country not naturally tolerant of strangers, he purposed penetrating into Persia and India. But the disturbed state of those parts of Asia prevented his fulfilling his intentions. He returned accordingly to Magna Græcia, once more to enjoy the society of the Pythagoreans. At length, having spent several years in these travels, he turned his steps homeward. We have no means of ascertaining the exact time which these travels occupied, or at what period of his life precisely he undertook the office of teacher of philosophy at Athens. From the epistle addressed to the friends of Dion, it appears that he was scarcely forty years of age when he first went to Syracuse;[1] so that probably not more than about ten years were taken up in his wanderings.

Dei*, viii. 11.) Clement of Alexandria, however, asserts that there existed a version of the Law prior to that of the Septuagint. *Strom.* i.; Euseb. *Præp. Evan.* ix. 6.

[9] Hence it was said by Numenius the Pythagorean, τι γαρ ἐστι Πλατων, η Μωσῆς Αττικιζων, "What is Plato, but Moses in Attic Greek."

The visit to Sicily here referred to, had for its object to explore the crater of Mount Ætna, and therefore properly belongs to that part of his history which we have just been tracing. But it had also very important bearings upon the future fortunes, both of himself and many others; so important, indeed, that Plutarch, following out a remark which occurs in the supposed epistles of Plato, attributes it to a providential arrangement, in order to the restoration of liberty to the Syracusans.[2] For it was at this time that he became acquainted with the elder Dionysius, tyrant of Syracuse, and Dion, whose sister Dionysius had married. He reclaimed Dion, who was then quite a youth, from a life of vicious indulgence, to habits of sobriety, and inspired him with an ardent love of philosophy. Thus began an intimate friendship between the philosopher and Dion, which subsisted unimpaired until the tragical death of the latter.

Through the influence of Dion, the tyrant Dionysius, who was himself a literary man and a patron of literature, was induced to receive Plato into the circle of his court. The result, however, whether it was owing to the jealousy of other philosophers who were then at the court of Syracuse, or to an excess of freedom of speech in Plato, and an ebullition of temper and disappointed literary vanity upon the part of Dionysius, was unfortunate. Dionysius was affronted at some words that passed at an interview with him, and was only prevented by the interposition of Dion from slaying the philosopher at the moment of exasperation. But still he did not remit his displeasure; for on suffering him to depart, he instructed the Lacedæmonian ambassador, Pollis, in whose vessel he was to be conveyed from Sicily, either to slay him on the voyage or to sell him as a slave; observing sarcastically, "that being a just man, he would be equally happy though reduced to slavery." Pollis is said to have so far lent himself to this cruel treachery, that he actually caused the philosopher to be sold as a slave, by landing him at Ægina at a time when a decree was in force there, sentencing to death every Athenian who should set foot in the island. From this shameful indignity, however, Plato was immediately relieved by the generous kindness of Anniceris, a philosopher of Cyrene, who happened to be at Ægina at the time, and paid the twenty minæ, the price of his redemption. And such, it is added, was the noble concern which Anniceris felt for him, that he could not be prevailed on to receive back the money from the friends of Plato at Athens, but refused it, saying "that they were not the only persons interested in the welfare of Plato."[3]

The story is related with circumstantial particularity, and so far bears the aspect of truth. Still it has been questioned, as inconsistent with the character of Dionysius, who, though despotic in the power which he possessed, and often cruel in his use of it, was a man of education and courtesy, and the patron of literary men. And the treachery of Pollis, as thus exhibited, has been regarded as altogether unlikely in the high-minded Spartan. Nor again do we find any allusion in the writings of the philosopher himself to so affecting an incident in his life. The story may be thought still more improbable, if the account be true that Dionysius presented him with a considerable sum of money, with which he was enabled, during his residence in Sicily, to purchase a treasure inestimable to him, the books of Philolaus the Pythagorean. These arguments, however, may be pressed too far. Individuals possessed of absolute power have often been found capable of deeds from which their own feelings, apart from that great temptation, would have shrunk: and sudden and most unreasonable and absurd outbreaks of violence, inconsistent with their general behaviour, are characteristics of such power. And as for the Lacedæmonians, we know that at the height of their civilization they were guilty of the acts of barbarians. Their extreme cruelty to the poor debased Helots is well known;[4] and in the Peloponnesian war they slaughtered indiscriminately all whom they met with at sea, even neutrals, and persons inoffensively engaged in the business of commerce.[5] Further, there are repeated instances of Greeks selling as slaves the free inhabitants of captured cities in their wars with each other.[6] There is no reason, at any rate, to question the general truth of the story, whatever may be thought of the particulars. There can be little doubt that the visit of Plato at Syracuse ended unsatisfactorily; that offence arose between the tyrant and himself; that he was treated with great indignity, and that he returned to Athens in disgust.[7]

From this time we may contemplate him as pursuing, with little interruption, the course of philosophical labour for which his whole previous life had prepared him. The term "Academy" is now familiar to every one as synonymous with a place of learning. How strongly does this mark the celebrity of a school, which has thus immortalized in vernacular language the grove of the hero Academus or Hecademus, the ground on which Plato walked, and, as he walked, imparted to the throng around him the riches of his genius, and taste, and learning! Here, in the most beautiful suburb of Athens, the Ceramicus, Plato possessed a small patrimony, a garden, where he fixed his abode, in the immediate vicinity of the grove, his daily resort. Here, amongst the tall plane-trees which shaded the walks, were assembled, year after year, the master-spirits of the age, whether in pursuit of knowledge for its own sake, or for counsel in the direction of public or private life,—the philosopher, the statesman, and the man of the world,—to converse with the Athenian sage, and imbibe the wisdom which fell from his lips. What an interesting assemblage must that have been which comprized in it, amongst other influential persons, and young men who afterwards rose to importance in their respective states, Demosthenes, Hyperides, Aristotle, Speusippus, Xenocrates, Polemo, Dion! At once you might see in the throng the young and the gay by the side of the old and the sedate; the stranger from some distant town of Asia Minor, or Thrace, or Magna Græcia, and the citizen of Athens; the tyrant of some little state learning theories of government and laws from the philosopher of the republic; and the haughty Lacedæmonian paying deference to the superior wisdom of an individual of a country which his own had humbled in arms.[8] Nor was the audience exclusively of the male sex. The wives and daughters of Athenian citizens, indeed, were not in that assembly; for custom excluded these. But the accomplished courtezan, whom the unnatural exclusion of the chaste matron from social intercourse had raised to importance in Grecian society, was there, seeking the improvement of her mind by joining in the discussions and listening to the instructions of the philosopher, and thus qualifying herself for that part which she had to sustain as an intimate with the men of the highest rank and most intellectual cultivation in Greece. The celebrated Aspasia had been at once the intimate of Pericles, and a hearer of Socrates; and Plato himself pays her the compliment of saying, that both Pericles and Socrates had taken lessons in rhetoric from her, as a most accomplished mistress of the art; to whom, indeed, Pericles had been chiefly indebted for his eloquence.[1] So now in Plato's own school of the Academia were found, amongst others of the same class, the beautiful Mantinean Lasthenea, and Axiothea of Phlius.

[6] *Ibid.*

[7] The conduct of Dionysius towards Philoxenus, the dithyrambic poet, for freely giving his opinion on the bad poetry of Dionysius, was very similar. See Diodorus Siculus, xv. 6, who also, in xv. 7, confirms the account of this treatment of Plato.

[8] In the Dialogue "on Laws," it is the Athenian stranger who instructs the Lacedæmonian and Cretan in the theory of legislation. Here we have probably a representation of what actually was seen in the Academia itself. Socrates is away; Plato speaks; Cretans and Lacedæmonians, among others, are the auditors.

Socrates attracted persons around him from all parts of the Grecian world, by the charm of his engaging conversation, and thus became in himself a great object of interest.[2] Plato made Athens itself also, even more than his own person, an object of interest to the civilized world of his day; converting it, from being only the centre of political intrigue and agitation to the cities of Greece, into a common university and common home for all. Compare what was said of Athens about half a century before, "that it was the nature of Athenians neither to keep quiet themselves, nor to suffer other people to do so,"[3] and its well-known character at that time of a "tyrant state,"[4] with the respect which Plato had won for it, when it became, not through the versatility of its citizens, and its inexhaustible resources, but by a truer title, through the lessons of virtue and wisdom, which it freely imparted to all, pre-eminently the School of Greece;[5]—and what an exalted opinion does the change now operated give us of the influence of Plato!

Isocrates had, at the same time, his school of rhetoric overflowing with pupils. Aristippus, also trained in the school of Socrates, was inculcating his scheme of ethics, which maintained the theory of pleasure as the chief good. But esteemed as Isocrates was for the gentleness of his life, and his skill as a master of rhetoric; and acceptable as the doctrines of Aristippus must naturally have been to a corrupt society; neither of these great names sufficed to obscure the greater name of Plato, or could rival the pretensions of the Academia to be the great school of philosophy, and literature, and civilization.

A mind so intensely occupied as that of Plato, would scarcely find leisure for taking part in the political affairs of his country. The profession of philosophy was not as yet indeed become entirely distinct; but the teaching of Socrates had greatly tended to render it so. The rigorous method of interrogation which called forth the latent difficulties on other subjects, could not but produce great distrust in those who laid themselves fully open to it, as to their own ability to manage the complex matters of public concern, as well as impress them with despair of success in that walk of exertion. Socrates himself avoided as far as possible all interference in the politics of Athens. Plato strictly followed his example. Accordingly, we find, in several places of his writings, a contrast drawn between the philosopher and the man of public life; and an indirect apology for himself, as one who kept aloof from the public assemblies and the courts.[6] He betrays indeed strong disgust, not unmixed with contemptuous feeling, at the state of misrule into which the democracy of Athens had degenerated in his day, and he was evidently glad to avail himself of the plea of philosophy to absent himself from scenes so uncongenial to his taste. Doubtless, independently of any political bias, he was glad to escape from the sycophancy and tumult of the popular assemblies at Athens, and to enjoy the calm shades of his beloved retreat. This was the sphere of action for which nature and his whole previous life had peculiarly fitted him. Here he could effectually diffuse the salutary influence of his philosophy, in counteracting, in some measure at least, the selfishness of the world. Here he could maintain an undisputed supremacy over minds, which (such was the impatience of all authority in those times) no mere external power could have so entirely subjected to the direction of an individual.

Through the influence, however, of his Pythagorean friends, with whom he appears to have held constant intercourse, Plato was prevailed upon, at the age of sixty-five years, to quit the retirement of his garden for a time, and pay a second visit to Sicily.[7] It was the policy indeed of the Pythagoreans, like that of the Jesuits in modern times, to keep up an active intercourse with society, whilst in their internal system they cultivated philosophy with the ardour of exclusive devotees. Socrates wished to govern the conduct of men by an appeal to their reason; convincing them of their errors and follies, and leading them to seek the means of informing themselves aright. The Pythagoreans, like the Jesuits, aspired to carry out their views by a moral hold over men in society; by taking part accordingly in the management of states, and by a secret influence over those in power. The accession of the younger Dionysius to the throne of Syracuse, and the opening presented for producing an effect on him through Plato's influence with Dion, the next in power to the tyrant, were opportunities which would not be lost by their watchful zeal. Such seems, if we may proceed on the authority of the Epistles, to have been the occasion of this invitation of Plato to Syracuse. We see, at the same time, that there was a struggle of factions at Syracuse at this period. The party opposed to Dion, in order to counteract his influence, obtained the recall of Philistus, a man distinguished alike as a statesman, a commander, and an historian,[8] and a strenuous supporter of the existing government, but then in banishment through the ingratitude and caprice of the elder Dionysius. The result was, that though the reception of Plato at Syracuse was most flattering, for he was welcomed with the royal pomp of a decorated chariot, and the celebration of a public sacrifice, his mission was ultimately fruitless.

At first everything seemed prosperous. The change wrought in the manners of the court is described as marvellous. Philosophy became the fashion; and the very palace was filled with the dust stirred up by the number of geometricians. Even the expulsion of Dion, which soon followed, through the successful intrigues of his enemies, did not at once estrange Dionysius from the philosopher. He would not indeed allow Plato to leave Sicily with Dion; but, using a gentle constraint over him, detained him within the precincts of the citadel; shewing him at the same time all respect, and hoping at last, as it seems, to bring him over to his interest. At length the attention of Dionysius was called to preparations for war; and Plato, released from his embarrassing situation, was enabled to return to Athens.

[7] Diogenes Laertius says, he went to Sicily on this occasion, in order to found a city according to the principles of his Republic, but that Dionysius failed in his promise of land and men for the purpose. But others, he adds, stated that the object of his visit was the liberation of the island from tyranny. In *Vit. Plat.*

[8] Cicero speaks of Philistus as a writer in the following manner: Philistum doctum hominem et diligentem. (*De Divin.* i. 20.) Catonem cum Philisto et Thucydide comparares? quos enim ne e Græcis quisquam imitari potest. (*De Clar. Orat.*)

He was not, however, deterred from once more making the trial, how far an impression could be made on the mind of Dionysius, and the restoration of Dion to his country effected; and, as on the former occasion, so now, he was chiefly induced to undertake the enterprise, by the earnest intercession of his Pythagorean friends. Dion himself was living at Athens, waiting the opportunity of returning to his country; and his relatives at Syracuse sent letters to Plato, urging him to use his exertions in behalf of Dion. Even Dionysius himself wrote a letter to him, entreating him to come, and promising satisfaction at the same time in regard to Dion. He also sent a trireme for him, with Archidemus, a disciple of Archytas, and others with whom the philosopher was acquainted, to render the voyage more agreeable to him.[1] For a while Plato persisted in declining the invitation, pleading his advanced age, for he was now sixty-eight years old;[2] but at length he gave way to these united solicitations. Dionysius, indeed, like his father, was fond of drawing around him men of eminence for literature and philosophy. At this time, amongst others of the same class at his court, were the philosophers Diogenes, Æschines, Aristippus, and some Pythagoreans. Plato might have not unreasonably hoped, therefore, that a mind delighting in such society, or at least ambitious of the reputation of being a patron of literature, might yet be influenced to sound philosophy. He was, besides, desirous of making an attempt to produce a reconciliation between Dionysius and Dion. Thus did he pass the Straits of Sicily a third time, to be a third time disappointed in the object of his voyage. Though he was welcomed, as before, with great splendour and demonstrations of respect, not only were his endeavours for the restoration of Dion unsuccessful, but he incensed the tyrant by venturing to intercede in behalf of Heraclides, a member of the liberal party at Syracuse, who was under suspicion of having tampered with the mercenaries. Still Dionysius was desirous of retaining the friendship of the philosopher. Plato was removed, indeed, from the garden in which he lived, under the pretence of a sacrifice about to be performed there by women, and placed in the quarter of the mercenaries. Such a situation was most unpleasant to him; as he could not but feel himself in danger amongst that lawless class, who naturally disliked him, as an enemy of the power which gave them employment and pay.[3] But this indignity was probably more the effect of the hostility of the opposite party against Dion, than an act of the weak tyrant himself. Plato, in his perplexity, applied to Archytas and the Pythagoreans at Tarentum, to extricate him from these difficult circumstances. At their instance, accordingly, Dionysius consented to the departure of Plato, and dismissed him with kindness, furnishing him with supplies for his voyage.

Thus did Plato once more return to Athens, heartily disgusted with the untoward result of his visits to Sicily.[4] Though the friend of Dion, the head of one great party at Syracuse, he had acted in Sicily consistently with his conduct at Athens, in not taking any active part in political affairs. Even Dionysius himself seems, throughout his conduct towards him, to have been jealous rather of his personal regard for Dion, than suspicious of any exertion on his part in the cause of Dion against him, and to have sought to detain him at Syracuse, not out of fear or ill will, but for the honour of the presence of the philosopher at his court. This is further evinced by the subsequent conduct of Plato. For, in the expedition which Dion planned and executed against Dionysius, he took no part; making answer to the invitation to join in it, "that if invited to assist in doing any good, he would readily concur; but as for doing evil to any one, they must invite others, not him."[5]

The remaining years of his life were gently worn away amidst the labours of the Academia. These labours were unintermitted to the very close of a long life; for he died, according to Cicero's account, in the act of writing; his death happening on the day in which he completed his eighty-first year. "Such," adds Cicero, "was the placid and gentle old age of a life spent in quietness, and purity, and elegance."[6] Another account, however, of his death states that he died during his presence at a marriage-feast.[7] And another account besides (evidently the invention of some enemy to his fame), attributes his death to a loathsome disease.[8] On his first residence in the garden of the Academia, his health had been impaired by a lingering fever, in consequence of the marshiness of the ground. He was urged to remove his residence to the Lyceum, the grove afterwards frequented by the school of Aristotle; but such was his attachment to the place, that he preferred it, he said, even to the proverbial salubrity of Mount Athos; and he continued struggling against the disorder for eighteen months, until at length his constitution successfully resisted it.[9] Adopting habits of strict temperance, he thus preserved his health during the remainder of his life, amidst the harassings of foreign travel, and the undermining assiduities of days and nights of study.

Plato was never married. He had two brothers, Glauco and Adimantus, and a sister, Potona, whose son, Speusippus, he appears to have regarded with peculiar affection and interest, as the destined successor to his school of philosophy. He inherited a very small patrimony, and he died poor, leaving but three minæ of silver, two pieces of land, and four slaves, and a few articles of gold and silver to the young Adimantus, the son, as it would seem, of his brother of that name.[10]

In person he is described as graceful in his youth, and, if the etymology of his name be correct, as remarkable for the manly frame of his body.[11] One circumstance, however, is mentioned, which detracts in some measure from his bodily accomplishments; the imperfection of his voice, which has been characterized as wanting in strength of tone.[12]

In regard to moral qualities, he was distinguished by the gravity, and modesty, and gentleness of his demeanour. He had never been observed from his youth to indulge in excessive laughter.[13] Several anecdotes are told of his self-command under provocation; as, for example, his declining to inflict the due punishment on a slave when he found himself under the excitement of anger.[14] A pleasing instance is given of his amiableness and modesty, at a time when his fame was at its height. Some strangers, into whose company he had been thrown at Olympia, coming afterwards to Athens, were received by him there with the greatest courtesy. All the while, however, they were ignorant who their host was. They merely knew that his name was Plato. On their requesting him to conduct them to the Academia, and show them his namesake, the associate of Socrates, they were astonished to find, by his smile and avowal of himself, that they had experienced so much unpretending kindness from the great philosopher himself.[1] Again, being asked by some one if there would be any saying recorded of him, he answered with the like modesty, "One must first obtain a name, and then there will be several."[2]

[13] Diog. Laert. in *Vit.* after Heraclides.

[14] Diog. Laert. in *Vit.* Seneca *De Ira.* The anecdotes themselves can hardly be regarded as original. Similar stories are told of others, as of Archytas. Ex quo illud laudatur Archytæ; qui cum villico factus esset iratior, "Quo te modo, inquit, accepissem, nisi iratus essem?" (Cicero, *Tusc. Qu.* iv. 36.)

The gravity of his manner was by some interpreted as severity and gloom. The comic poet Amphis complained of him, that "he knew nothing but to look sad, and solemnly raise the brow." Aristippus charged him with arrogance. It is no wonder, indeed, that, in contrast with the coarse freedom of Diogenes, and the excessive affability of Aristippus, he should appear haughty and reserved. But that this character did not really belong to him, we may judge from the social humour which mingles even with the sarcastic touches of his Dialogues, and from the anxiety which he shewed to correct such a disposition as a fault in Dion. His favourite pupil Speusippus was distinguished by the opposite quality of a lively temper; and to his especial direction we find Plato sending Dion, that he might learn, by the conversation and example of Speusippus, a more conciliatory and agreeable mode of address.

The instance given of his vanity in putting himself forward at the death of Socrates, as competent to retrieve the great loss in his own person alone, bears evident marks of a calumny. It may be so far true, as it represents a desire upon his part to console his brother disciples under their common affliction. But as an evidence of an assumption of superiority over them at such a moment, it accords little with that feeling of dismay for themselves, under which he, in common with the rest, fled to Megara as an asylum; or with his indisputable affection for the person of Socrates, and veneration for his wisdom and talents.

Again, the strictness of Plato's philosophical profession, amidst the general dissoluteness of manners at Athens, was construed by some who had an envious eye on his reputation, as only an affected austerity. It was complained of him, that his life did not answer to the high requisitions of his moral teaching.[3] Two of his brother disciples in the school of Socrates, Antisthenes and Aristippus, imputed to him the grossest licentiousness. The former taking offence at Plato for objecting to a treatise, which he proposed to read, on the Impossibility of Contradiction, vented his spleen in a most abusive dialogue, which he entitled Satho, intending at once by that term a satirical play on the name, and a stigma on the character, of the philosopher. These calumnies are in some measure supported by the tenor of certain epigrams attributed to Plato, and by passages of his Dialogues, which display a license of impure allusion, shocking to the feelings of the reader, in these days at least. His calumniators then found occasion for their scandal, in observing amongst those by whom he was surrounded, the young and the handsome. But though we may see much to reprobate in such passages, and painful as the impression is which they leave on the mind, as evidences of the deep corruption of human nature, we are not warranted in regarding them as conclusive of corresponding immorality of conduct in a writer of his age and country. They shew, indeed, that the writer has not escaped the contagion of the vicious atmosphere which he breathed, and they are of course a great drawback in our estimate of the purity of his sentiments and character. But we ought to set off against them the high tone of religious and moral feeling which is the general characteristic of his philosophy; the beacon which it holds up to warn men of the debasing allurements of pleasure, and of the misery consequent on the indulgence of passion; and its glowing exhortation to seek for true happiness, not in externals, or by aiming at a mere human standard of virtue, but by internal purification, and by imitation of the perfections of the Deity.

Much has been said on the absence of any reference to Xenophon in the Dialogues of Plato. Xenophon, in his *Memorabilia*, has spoken of Plato, and alluded to the affection with which Plato was regarded by Socrates.[4] But Plato has not availed himself of any opportunity of paying the like compliment to Xenophon. This silence cannot, perhaps, be entirely accounted for, without supposing that there was a feeling of literary jealousy on the part of Plato. But there are some considerations which may partly account for Xenophon's not appearing as an interlocutor in the Dialogues. Xenophon, though a man of philosophical mind, evidently attended the teaching of Socrates, not to learn the art of disputation, or for the indulgence of a speculative curiosity. When he philosophized, it was as a man of the world, acquainting himself with human nature, with the manners and opinions of men, in order to his own conduct in life. He was not one of those eager and flippant sciolists, whom Plato takes delight in submitting as apt experiments to the interrogatories of Socrates. Nor was he, again, a devotee of science, like the wise Theætetus, the interesting person who gives occasion to the dialogue of that name, and whom in some points he resembled. He would not therefore naturally be selected by Plato, in order to the carrying on of discussions intended for the development of his philosophy. It is remarkable, that Plato has only in two places even alluded to himself; in the *Phædo*, to explain his absence from the death-scene in the prison;[5] and in the *Apologia*, as amongst those present at the trial of Socrates, and capable of giving evidence as to the nature of those instructions which Socrates addressed to the young.[6]

Such was the character of this eminent man. His distinguished career exposed him to the shafts of envy and detraction; and the high aspirings of his mind were clogged and weighed down by that corrupt heathenism with which he was surrounded. Still his reputation for wisdom and virtue stands above all these attacks and circumstances of disparagement. The more we converse with him in his writings, the more we are charmed by the deep feeling of natural piety which pervades his philosophy as its master-thought, and by the sound practical wisdom which shines forth from them as the real character of the man, reclaiming and subduing the wild aberrations of his speculative fancy.

His remains were buried in the place which he had ennobled whilst living. Nor were they unattended by the

Plato's Writings and Philosophy.

customary tributes of honour and affection. Aristotle, who had been his constant disciple during the last twenty years preceding his death, displayed his veneration for his preceptor by consecrating an altar to him. A festival, called after him Platonea, was instituted in honour of him, and celebrated annually by his disciples. A statue, dedicated to the Muses, was afterwards erected in the Academia by Mithridates the Persian. He had not, indeed, been dead but a very few years, when the great celebrity of his name called forth from his nephew and successor, Speusippus, an express work in his praise. Seneca further tells us of a singular mark of honour which was paid to him on the very day of his decease. There were some Magi, he relates, at Athens at the time, who, struck by the singular circumstance of his having exactly completed the perfect number of nine times nine years, performed a sacrifice to him, esteeming him on that account to have been more than man.[1] The story is evidently the invention of his later admirers. It is referred to here, as a testimony of the enthusiastic admiration with which his name has been ever attended. To the same feeling must be ascribed the fiction of the discovery of his body in the time of Constantine the Great, with a golden tablet on the breast, recording his prediction of the birth of Christ, and his own belief in the Saviour.[2]

PLATO'S WRITINGS AND PHILOSOPHY.

The writings of Plato obtained an early popularity. Already, during his lifetime, copies of them appear to have been circulated. An iambic line, λογοισιν Ἑρμοδωρος ἐμπορευεται, proverbially applied, long after the time of Plato, to those who made a traffic of the writings of others,[3] shews that there was an immediate demand for them in Greece. The Hermodorus here referred to, was one of his hearers, who is said to have sold the writings of the philosopher in Sicily for his own profit. The fact of their early circulation is further evidenced, if it be true, as has been stated, that complaints were made by some of the persons whose names appear in the Dialogues, and even by Socrates himself, of the manner in which they had been represented in them by Plato.[4] It is very probable, also, that during the long time in which he was publicly teaching at Athens, and, doubtless, recurring frequently to the same topics of discussion, considerable portions of what he delivered orally, were treasured up in the memory of some who heard them, and afterwards written down, and thus published to the world without having received the finishing touches of the author's hand. The practice, indeed, of thus carrying off the oral lessons of the philosopher is alluded to by Plato himself in passages of his writings, as in the *Phædo*, and *Theætetus*, and *Parmenides;* where the dialogue is related by some one remembering what has passed in conversation on a former occasion. This circumstance may, at once, account for the comparative inferiority of some of the Dialogues in point of execution, and for the fact that some have been passed under his name which are not really his; whilst we have, at the same time, a very considerable collection of writings authenticated by testimonies descending from his own times.

It is by no means necessary for our purpose here (which is to obtain a just general view of the character of the philosopher and his writings), to enter into the criticisms by which doubts have been thrown on particular Dialogues, and on different Dialogues by different critics, out of the number commonly included amongst the genuine works of Plato. We may only remark, that these doubts do not rest on external testimony, but are drawn from considerations of the internal character of particular writings, which have been judged inferior to the rest in matter and execution. Nor is it necessary that we should discuss the various theories proposed for connecting the several Dialogues, and tracing in them the gradual formation and development of the philosophical system of the author. This inquiry certainly has its interest; and could we arrive at any clear results in the prosecution of it, it would be valuable, for the light which it would throw on the interpretation of the philosophy of Plato. But though we can discover a connection between several of the Dialogues, like that of a series of discussions on the same subject, it is not possible to decide on the order in which the points discussed presented themselves to the philosopher's mind, or which we are to regard as the more mature expression of his doctrines. This inquiry further demands a decision of the agitated question concerning the double teaching practised in the ancient schools, known by the technical division into esoteric and exoteric, or mystic and popular; the former addressed to the mature disciple, the latter to the novice or general hearer. There are undoubtedly marks of a recognition of this distinction throughout the writings of Plato;[5] and it is also probably referred to by Aristotle, when he speaks of the "unwritten doctrines" of Plato.[6] But we cannot practically employ it in determining the relative value of particular discussions or statements in his writings, without involving ourselves in a maze of theoretic disquisition, and ending at last, perhaps, in absolute scepticism respecting his doctrines.

But there is a particular class of writings attributed to him, which would possess a peculiar interest for us, if we could establish their genuineness; respecting which, however, the severe verdict of modern criticism compels us to hesitate in pronouncing on their genuineness. We mean what are commonly published in the editions of his works as the Epistles of Plato. By some the question has been regarded as settled beyond controversy, against their reception.[7] The style of their composition has been judged to be quite below the character of Plato's mind. The apologetic tone of the chief part of them has also been considered as evidence of their having proceeded from friends or disciples of Plato, vindicating his character from misrepresentations in regard to his intercourse with the court of Syracuse. But though we may allow weight to these considerations, they are not sufficient peremptorily to decide the question against the Epistles; particularly as we have in their favour the authority, not only of Plutarch, who founds much of the narrative in his Life of Dion upon them, but of Cicero, referring to them and quoting them expressly as writings of Plato.[8]

Perhaps no philosophical writer has ever received so early and ample a recompense of his labours, not only in the reception and circulation of his writings, but in the still more glorious tribute of the spread of his philosophy, as Plato has received. We have mentioned the ordinary marks of admiration which accompanied him during his life and after his death. A more enduring monument was reserved for him in the foundation of the school of Alexandria, not many years after his voice had ceased to be

Plato's Writings and Philosophy.

Plato's Writings and Philosophy.

heard in the groves of the Academia. There, as in a fitting temple, on the confines of the Eastern and Western Worlds, was enshrined the philosophy which had moulded into one the philosophical systems of the East and the West. And though, in the course of things, the infusion of Eastern Philosophy predominated at Alexandria, it was still under the venerated name of Plato that the new system was taught. The disciples of the Alexandrine school were proud to call themselves Platonists, and to regard themselves as interpreters of the doctrines of Plato, whilst they altered and disfigured those doctrines. Here, then, was erected the proper monument to his fame. Meanwhile, in the Academia, teachers in regular succession transmitted their inheritance of his name, and by the charm of that, prolonged a feeble existence. For the spirit which had formed and animated the school had fled with him; and the Middle and New Academics only attested, by their lingering decay, the strength of the foundation on which they had been built. How great the influence of Plato was on the philosophy of the Romans, needs not to be told to those who are even slightly acquainted with the philosophical writings of Cicero. And even when Christianity threw into the shade all systems of man's wisdom, the only philosophy which maintained its credit at the first, was that of Plato. Christian teachers were found, not unwilling to own that there was great accordance between his doctrines and the revealed truth. Whilst, on the one hand, there were disciples of the philosopher who claimed for him all that was excellent in the Christian scheme, there were Christians who asserted, that he had learned his superior wisdom from the elder Scriptures. All this shews the hold which his name still retained over the minds of men at this period. The great father of the Western Church, St Augustin, avows himself a warm admirer of Plato. He concedes the approximation of the Platonists to the Christian doctrines; affirming that all other philosophers must yield to those who had speculated so justly as they had respecting the Chief Good.[1] Afterwards, indeed, we find Aristotle supplanting Plato in favour with the Christian controversialist. The struggle had been for some time between their respective advocates, which of them should obtain the lead in the Christian schools. But Plato, on the whole, had the mastery, though the result of the struggle was an eclectic system, in which the principal differences of the two philosophers were studiously reconciled. In fact, we may consider Platonism as in the ascendency in the Christian schools, until the period of Scholasticism, that is, until the twelfth and the following centuries, when the discipline of argumentation was at its height in the Church, and with it the study of Aristotle's philosophy. Even then the theories of Plato maintained their ground. The speculations pursued by members of the Church continued to be for the most part Platonic in their principles, though they were conducted and modified by the dialectical method of Aristotle.

What, then, was the character of this philosophy, it will naturally be asked, which both rendered it so attractive to those amongst whom it arose, and also secured for it such an immortality?

It is a very remarkable circumstance that, as far as we know, Plato should have escaped all censure at Athens on account of his philosophy, when other philosophers, who, like him, became centres of popular attraction, were the objects of extreme persecution. It is the more remarkable, as not only his master experienced such persecution, but his immediate disciple, Aristotle, was forced to fly from Athens to escape the storm with which he was threatened. Coming between these two, and enjoying, at the height of his popularity, an influence perhaps surpassing that of either, he yet was suffered to wear out his life unmolested, amidst the tranquil labours of his school.

The only evidence to the contrary of this is an unauthenticated anecdote, told by Laertius, of Plato's having accompanied Chabrias to the citadel of Athens, and shewn his zeal in support of that general, under the capital charge brought against him. Upon this occasion, it is said, Crobylus, the sycophant, meeting him, observed, "Are you coming to plead for another, as ignorant that the hemlock of Socrates awaits you too?" to which he replied, "When I served my country in the field I underwent dangers, and now in the cause of duty I undergo them for a friend."[2]

But though we may refuse to believe this story, it is quite evident, that the condition of philosophy at Athens was not without its obloquy and danger even in its most flourishing times under Plato. We may gather from many passages of the writings of Plato, that the cause of philosophy still needed defence, and that great caution was required on the part of those who publicly professed the study of it. A re-action indeed had taken place in favour of philosophers, in consequence of the severity with which Socrates had been treated; and the assailants of Socrates suffered retribution from the popular feeling. Still there was in the mass of the Athenian people a strong antipathy to philosophy, from their ignorance of its real nature. They had been taught to regard philosophers as idle and mischievous drivellers, ever prosing about nature and the phenomena of the heavens, and as contemners of the gods.[3] They had seen also how some of those to whom Athens owed her greatest calamities, had been amongst the students of philosophy. Alcibiades, for example, had been a hearer of Socrates; one of singular natural endowments, in the formation of whose mind Socrates had taken especial pains, and who might therefore be regarded as the test of what philosophy could effect. The people had loved him as their spoiled child, in spite of all his follies; but they had felt also the mischief and misery of his wild career of ambition; and they threw the blame on his instructors, and the system in which he had been trained. Again, a great prejudice had been excited in the public mind against philosophy in general, from the many low and mercenary professors of it with which Greece abounded; minute philosophers, patronized by the public for their temporary services in teaching the arts of public life, but who produced ignominy and disgust to the true profession by their unworthy monopoly of its name. Add to this, that popular opinion had been corrupted by the false teaching, which had been so long and extensively at work throughout Greece. Erroneous principles of judgment and conduct had taken root in the public mind; or, to describe the case more correctly, all principles were unsettled, and the state of the public mind was a state of inward anarchy and insubordination. A philosopher, therefore, seriously devoted to his profession, and pursuing it with a single eye to the advancement of truth, was necessarily regarded with suspicion and dislike. For it is a natural propensity of the mind to adhere to what is established, whether it be good or evil, simply because the transition is easy, and no effort of thought is required, no trouble of self-examination imposed, no censure of self exacted; and what is inveterate in their own minds passes with men for the oldness of truth and nature. A reformer, therefore, is always an object of aversion; and no reform is successfully accomplished, until it has worked its way by subduing the prejudices which it has to encounter at the outset. Not only was the opposition to sound philosophy produced in the minds of the vulgar by this distemper of public opinion; but even the better part of society, the more educated and reflecting members of the community, were infected by it. The majority of these would be deterred from taking up a profession exposing them to so much dislike and risk. Some of them, too, with a view of standing well with the mass of those amongst whom they lived, and promoting their own interest, would avail themselves of the popular clamour against philosophy, cry down the pursuit of it as innovation and danger, and make it their business to exaggerate, instead of counteracting, vulgar prejudices on the subject.

These obstructions to the teaching of philosophy are pointedly referred to by Plato, as existing in his time, and demanding his attention, in order to the success of that mission of reform which he had undertaken. He treats the vulgar prejudice against philosophy as not altogether unreasonable,[1] in consequence of the perverse opinions which had been popularly inculcated; and endeavours to disarm the public hostility, by alleging the causes of the disrepute into which philosophy had unjustly fallen. Alluding, as it seems, particularly to the instance of Alcibiades, he points out, that it is not philosophy which corrupts the young, but the passions of the young and noble spirit which pervert the means of good to the greatest mischief. None but those of the highest order of talent and natural gifts are fully susceptible of its influence; but then these are the very cases, he observes, which are also capable of the most mischief, through their greater susceptibility of the seductions of the world. There cannot but be objections against philosophy, he further observes, as long as the mass of mankind is, as it is found, incapable of appreciating real essential good for its own sake; and as long as those of superior nature, who should be its devoted friends, and examples of its influence, are drawn away from it in pursuit of popular opinion. He endeavours, accordingly, to evince that there is no just ground for alarm, at least in those days, at the power of philosophy. It was now deserted and helpless, fallen amongst those who were not its own people. If disgrace now attached to philosophy, it must be imputed to the unworthy alliance into which it had been forced. The mean artisan, who has made his fortune, now quits his prison, and decks himself out, and aspires to the hand of the daughter of his master in her poverty and destitution.[2] It was no wonder, therefore, that such spurious fruits, of so unsuitable alliance, were then seen in the world, and that the few who clung to the true profession were like strangers in the world, living away from public affairs, as unwilling to join in the general iniquity, and unable to resist it effectually by their single strength.[3]

If Plato thought it necessary thus to apologize for the pursuit of philosophy, it is clear that there was yet reason to apprehend an outbreak of violence against its professors. In fact, however, he appears not only to have escaped all such outrage, but, whilst he propagated, by his oral teaching and his writings, a system of doctrines directly contrary to the impure morality and superstition established around him, to have enjoyed an esteem beyond that which any other teacher on the same ground ever obtained.

The explanation of this is in a great measure to be sought in the circumstances under which his philosophy was formed and matured, and to which it was peculiarly adapted.

What Themistocles admitted truly of himself when he answered, that he should not have achieved his glorious deeds if Athens had not been his country, was as truly applied by Plato to himself, when he enumerated amongst his causes of gratitude to the Gods, that he was born an Athenian.[4] For his philosophy was eminently Athenian. Viewed at least as we have it in his writings, it was the expression, by a master-mind, itself imbued with the spirit of the age, but rising above that spirit by its intrinsic superiority, of those tendencies of thought and action, which had been working in Greece, and especially at Athens, the centre of Grecian civilization.

The Peloponnesian war terminated with leaving Athens humbled before the confederacy, which the hatred and jealousy of her power had leagued against her. But the loss of her ascendency in Greece was not the worst evil brought on Athens by the result of that war. The machinery of faction, by which the war had been principally carried on, produced the most mischievous effects on the character and happiness of the Greeks at large; aggravating the symptoms of evil already existing in the constitutions of the several states, and, not least, in that of Athens. Not only did the insolence of the Athenian democracy gain strength in the result, and rise beyond all bounds, but the excesses in which party spirit had indulged, drew into prominence the selfishness and ferociousness of a demoralized people. Then might be clearly seen the levity and licentiousness of men, who, living amidst constant hazards, had learnt to regard nothing beyond the enjoyment of the passing hour; the cunning and cruelty engendered by mutual distrust; and the wanton contempt of all law and religion, prompted by the sight of the calamities which the tempests of social life scatter indiscriminately on the good and the evil. On this stock of corruption, speculative irreligion, and speculative immorality, had also grown up as its natural offshoots. Men were found hardening themselves against the reproaches of conscience and the fear of retribution, by arguing against the fundamental truths of religion and morals. In religion, it was contended that there were no Gods; or that if the existence of a divine power were conceded, there was no Providence over human affairs; or, lastly, that if there were a Providence, the wrath of the offended Deity was placable by the prayers and sacrifices of the offender. In morals, the question was debated, whether all was not mere matter of institution, and the device of the weak against the stronger power; and whether right might not change with the opinions of men.

This state of things had produced and fostered a spurious race of philosophers, familiarly known by the name of the Sophists; a name, not at first implying that disrespect, by which it afterwards characterized the pretensions of those to whom it was given. For the Sophists evidently were not the primary corruptors of the public mind in Greece, but themselves the offspring of that moral chaos, which resulted from the internal disorders of the country, and which they sustained, as its own children paying the recompense of their nurture to their genuine parent. They were an evidence of the corruption having reached the higher classes of society; for their instructions were sought by those who could pay for them, and who desired to qualify themselves for office and power in the state. Going about from place to place, and domesticating themselves wherever they could obtain a reception, they undertook to render all that flocked to them adepts in the arts of government, and even in virtue. The pretension would have been absurd and extravagant, but for the prevailing looseness of opinion on moral subjects.[5] But when right was understood as nothing more than what happened to be instituted and in fashion, there was an opening to every unprincipled teacher to adapt his moral lessons to the varied requirements of each distinct society.[1]

[5] *Rep* vi. p. 85.

At no place were these universal teachers more cordially received than at Athens. The anxiety with which an expected visit from any one of greater note among them was expected at Athens, and the zeal with which the young hastened to see and hear the wise man on his arrival, are depicted in lively colours by Plato. At Athens, evidently, if anywhere, the Sophist felt himself at his proper home. There was his readiest market. Herodotus may justly have been surprised at the success of so vulgar a deception at Athens, the seat of literature, as that practised by Pisistratus, when he exhibited to the people a woman of great stature, arrayed in full armour, and pompously borne in a chariot into the city, as the goddess Minerva, reinstating him in her own citadel.[2] It would have been still stranger if these impersonations of Athenian wisdom had not succeeded in imposing on the understanding of Athenians. For their minds were in that fluctuating state, which disposed them to receive every various form. They were subject to chance-impressions from the last teacher. Their general cultivation of mind, and taste for literature, prepared them for listening with pleasure to exhibitions of rhetorical and dialectical skill, such as the Sophists gave. And from admiration of the skill thus displayed, the transition was natural to consider that, as the only wisdom, which was capable of maintaining both sides of a question with equal plausibility, and that, the only virtue, which could shift and accommodate itself to every expedient with equal satisfaction.

Yet the Athenian was not entirely the creature of those circumstances, which had so considerably modified his character. He yet retained some traces of that high feeling so beautifully touched by his own tragic poet, when that poet speaks of "the pious Athens," and appeals to the ancient associations of religion which consecrated the land. Religion indeed had acquired the name of superstition, or the fear of supernatural powers, δεισιδαιμονια; but even this marks that there were some who cherished, though in that degenerate form, a veneration for the truths of the Divine Being, and the Divine agency in the world. Nor was the Athenian ever insensible to his pride of birth, and rank among those of the Grecian name.[3] He dwelt on the recollections of a remote antiquity of origin, as distinguishing him among the members of the Greek family. He claimed to be the offspring of the Attic soil, αὐτοχϑων, whilst others were descended from successive immigrations of strangers. Amidst his fickleness, and susceptibility of every passing impulse, he yet felt himself strongly influenced by his veneration for the past, and loved to connect himself with the ancient glories of his country. In the Athenian character, accordingly, may be observed the union of extremes; devoutness of deep inward feeling, accompanied with superficial irreligion and profane dissoluteness of morals; a mercurial temperament, ever eager for change, floating like a light cloud over a deep-rooted reverence of antiquity, and the tradition of ancestral wisdom and virtue.

Now, on accurately studying the writings of Plato, we find them, both, a reflexion of this state of the public mind at Athens, and a corrective of it. Full of imagination and of severe subtile thought, they are formed to attract and fix the attention of the literary Athenian. Bringing the Sophist on the scene, and giving sketches of the social life of Athens, and making conversation the vehicle of his instructions, Plato in a manner transferred to his own teaching, what was every day witnessed at Athens in the professorial exhibitions of the Sophists themselves. His philosophy, a counterpart, in its way, to the drama of the comic poet, instructed the people, at once, through their wisdom and their folly. As Aristophanes spoke to them under the mask of folly, and gave utterance to lessons of severe wisdom under that mask; so Plato, on the other hand, put on the mask of the sage, and in grave irony ridiculed and exposed the light-hearted folly of his countrymen. Both were wiser than they seemed to the outward observation; as was indeed the volatile Athenian, to whom they addressed their counsel. Both presupposed that delicacy of perception and quick tact in their fellow-citizens, which would be flattered by such indirect modes of address, and would, at the same time, appreciate the jest of the one, and the irony of the other. Both speak with the freedom of the democratic spirit. But the counsel of Aristophanes is that of the privileged jester of the sovereign-people amidst festal scenes and the enthusiasm of mirth; whilst Plato appeals to the Athenian at the moment of quiet, serious reflection on the surrounding folly, and treats him as a contemplative spectator, rather than himself an actor in it.

Before the time of Plato, there were no philosophical writings which answered the requisitions of the Athenian mind. There were poems of the early philosophers. There were didactic writings of the later Pythagoreans, and even dialogues discussing speculative questions. Anaxagoras, too, whose name was well known at Athens, had published a treatise of philosophy.[4] But none of these, if they were even accessible to the Athenian, were calculated to attract his attention. The philosophical poems differed nothing from prose but in the metre, and were exceedingly dry and uninviting to the general reader. The books of Pythagoreans were very few, at least at this time, and hardly known to any but the devoted student of philosophy.[5] Nor would the dialogues of Zeno or Euclid, concerned about mere logical subtilties, or the physical discussions of Anaxagoras, possess any charm for the lively Athenian. Even afterwards, the instructive writings of Aristotle did not obtain that reception which could save them from a temporary oblivion. But the dialogues of Plato supplied exactly what was yet wanting in this department of Athenian literature. They were the proper development of the philosophical element in the genius of the people. The shrewd practical talent of the Athenians had been strikingly exhibited in the successful achievements of their great generals and statesmen, and in the lead of Athens itself amongst the states of Greece at the close of the Persian war. Their taste in arts, and poetry, and general literature, had put forth splendid fruits in the works of Athenian artists, Athenian masters of the drama, and of history. But their genius for abstract speculation as yet had nothing which it could claim as strictly its own. Socrates indeed laid the basis for such a work. During the half century preceding the appearance of Plato as the leader of a school of philosophy, Socrates had been engaged as a missionary of philosophy, awakening the curiosity of men; turning their thoughts to reflection on themselves, as creatures endued with moral and intellectual faculties; and inspiring them with longings after some information on questions relating to their own nature, and a taste for discussions addressed to the resolution of such questions. Plato succeeded him, and carried the philosophical spirit, now fully called into action, to its result. His works accordingly display this spirit at its maturity; exemplifying at the

Plato's Writings and Philosophy.

Plato's Writings and Philosophy.

same time that peculiar combination of qualities which formed the Athenian character. Thus are they at once serious and lively, abstract and imaginative; full of deep thought and feeling intermingled with gaiety and humour; instinctive with the awe of religion and ancient wisdom, whilst they present also an image of Athenian versatility, and frivolity, and love of change. They convey indeed a strong rebuke of the vices of the times. They draw, in no softened colouring, outlines of the evil and misery resulting from the profligacy of existing governments, and the excesses of individual cupidity; the two great causes assigned by Plato for the prevailing evil of his times. But these lessons were calculated rather to interest the hearer or reader by their faithful representation of manners, than to alienate him, as we might at first think, by the justness of the censure. Athenians would give their attention to such descriptions, as they did to the invectives of their orators,[1] acknowledging the general truth of the representation; and each, at the same time, taking no offence at what he applied to others, and to every one rather than to himself. Philosophy too, taught, as by Plato, colloquially, was such as peculiarly to suit the taste of the Athenian, whose life was in the agora, or the ecclesia, or the courts of law; and who regarded the interchange of words as no unimportant ingredient in everything that he had to do.[2] Such conversation, too, as that of Plato's Dialogues, elegant conversation, steeped in the well-spring of Grecian literature, and expressed in language such as Jove, it was said, might use, and adorned with the charms of an exquisite musical rhythm, could not but be attractive to Athenian ears. We may see, accordingly, in these circumstances, at once, an occasion for the existence of such writings as those of Plato, and a reason of the peculiar mould in which they were cast, as well as of the success which attended them.

Not only, however, was the general character of his philosophy, as viewed in connection with the writings which convey it, derived from such influences; but the internal structure of it was the natural result of the peculiar education of such a mind as his, under the circumstances to which we have referred. His philosophy was essentially dialectical or colloquial; an examination and discussion of systems, and doctrines, and opinions. According to his notion, the true philosopher is the dialectician; the investigator, who has fought his way, step by step, through every argument capable of being adduced in support of a particular opinion, refuting those that are unsound, until at length he has found rest in some position that cannot be shaken.[3] Hence he is the disciple of no particular system of philosophy, whilst he brings all systems under his survey, and compels all to pay a tribute to his stock of truth, by discussing them, and rejecting in them what will not abide the test of examination. We have seen that he was engaged in studying the doctrines of Heraclitus, and of the Pythagoreans, and of the other schools, whilst he was also a hearer of Socrates. He had thus begun in early life to analyse different systems by the searching method of Socrates; and his mature philosophy was only the same proceeding more deeply imbibed in his own mind, more extensively carried on, and more vigorously applied. So far, indeed, does the colloquial spirit predominate over his philosophy, so entirely dialectical is it in its whole internal character, that it leaves on the mind of the reader more an impression of a series of discussions, in order to the determination of the questions considered, than the conviction of any thing positively determined. Hence it is that Cicero, speaking of Plato's writings, says, that "in them nothing is affirmed; and much is discoursed on both sides; everything is inquired into; nothing certain is said."[4] So also Sextus Empiricus raises the question, in what respect the philosophy of Plato differs from that of the Sceptics.[5] And again his doctrines have been characterized as brilliant clouds, which we seem at the point of grasping, when they vanish from our hands. This effect is doubtless partly to be ascribed to the disguise of his irony; to the artist-design which presides over his whole instruction. But it is also the proper effect of that dialectical philosophy which is worked out in the Dialogues. Whilst he is a consummate artist throughout, he is also illustrating the lessons which he had learnt from Socrates, by bringing false opinions to the test of discussion, and leaving truth, for the most part, to be collected from refutation of error, rather than positively enunciating it, or exactly defining it.

For when we come to examine his philosophy more closely, we find, that it begins and ends, like the lessons of Socrates, with a confession of the ignorance of man. Socrates had led him to perceive how much was taken for granted in the popular opinions and systems of philosophy; how even those who had a reputation for wisdom and talents took up principles which they had never examined, and which they could not satisfactorily account for, or defend, when pressed in argument. Imbibing, accordingly, the spirit of the Socratic method, he did not endeavour to *teach*, in the proper sense of the term, so much as to explore and test the minds of men; to ascertain, how far they really understood the doctrines and opinions which they professed. The fundamental error of the Sophists was, that they assumed all current opinions to be true. They did not think it necessary to examine this preliminary; whether the opinions on which they built their fabric of knowledge were true or false. It was enough for them, that certain opinions were *actually* held; and to these, as given principles, they directed their whole system of teaching. Their teaching, accordingly, was entirely προς δοξαν, relative to opinion; and it must, consequently, stand, or fall, as existing opinions could be maintained or impugned. Now, with Plato, as with Socrates, the investigation of this preliminary point (that is, whether existing opinions are true or no), is everything. The presumption that they are true, is what he will by no means admit. He demands a positive evidence of them. And as the presumption of their truth is a bar to all inquiry concerning them, he commences with the opposite presumption of their falsehood, or at least a confession on the part of the inquirer, that as yet,—until he has investigated,—he does not *know* the *truth* of his opinions.

For the same reason, he avoids all dogmatism in his conclusions. Those might aspire to communicate the knowledge of new truth to the mind, who, as the Sophists did, assumed that knowledge was entirely subjective; or who held that any opinion which could be produced in the mind, was simply true, was really known, because it was there. But as Plato denied the truth of Opinion, if it had no other evidence, but that of its mere presence in the mind; so, neither would he concede that any process of the mind in itself, or any argumentative and persuasive instructions, could produce, *by their own force*, a conviction of truth in the mind. In other words, he required the student of philosophy, not only to begin, but to end, with a confession of the ignorance of man.

We have an apt illustration of this in the dialogue entitled the *First Alcibiades*. There Socrates is introduced, questioning Alcibiades concerning his plans of life, and shewing how entirely he had presumed on his knowledge of matters with which he was unacquainted; and that until he could be brought to feel and confess his ignorance, there was no possibility of his being able to direct himself or others aright.

---

[1] Thucyd. iii 38; Demosth. *passim*.

[2] 'Ου τους λογους τοις ἐργοις βλαβην ἡγουμενοι, ἀλλα μη προδιδαχθῆναι μαλλον λογῳ προτερον, ἢ ἐπι ἁ δεῖ ἐργῳ ἐλθεῖν, κ. τ. λ. (Thucyd. ii. 40; also iii. 42.)

[3] 'Ωσπερ ἐν μαχῃ δια παντων ἐλεγχων διεξιων, κ. τ. λ. (*Rep.* vii. p. 167.)

[4] Cic. *Acad. Quæst.* i. 12.

[5] Sex. Emp. *Pyr. Hyp.* i. 33; Diog. Laert. in *Vit. Plat.* 33.

In the *Meno*, the same is illustrated by the comparison of the effect of the searching questions of Socrates, on the mind of the person submitted to them, to that of the torpedo. Meno says, he had thousands of times, and to many a person, and with much credit to himself, as he thought, spoken on the subject of virtue; but on conversing with Socrates, he was quite at a loss now to say even what virtue was.

To the same purport is the general application by Socrates in the *Apologia*, of the oracle which pronounced him the wisest of men. The oracle, he observes, had only used his name by way of example, as if it had said, "He, O men! is the wisest of you, whoever, like Socrates, is convinced, that he is in truth worthless in respect of wisdom."[1]

The method of Plato, accordingly, is the reverse of didactic. The Sophists could employ a didactic method; because they assumed principles as true, from which they might proceed to argue and persuade. But this was precluded to Plato, assuming, as he did, that all opinions demanded a previous examination. It was necessary for him to extort a confession of ignorance, to make men sensible of the difficulties belonging to a subject. It only remained, therefore, for him to proceed by Interrogation. In a colloquial philosophy, Interrogation is what experiment is in physical inquiry. It is the mode of discovering what the real state of a person's mind is, in regard to the opinions which he professes. The whole art of Socrates consisted in putting questions to the person with whom he conversed, so that an answer bearing on the point in debate might be elicited; that the grounds on which a given opinion was held might fully appear; and the person's own answers might open his mind to see it in its proper light. This method Plato has followed out in the interrogatory of his Dialogues. Under such a method of philosophy, the answerer is brought to teach himself. The lesson thus given by the philosopher, consists wholly in the questions which he puts. He preserves, from first to last; the simple character of the inquirer; and he *pronounces* only so far as he approves or rejects the answer given.

The popular opponents of this method called it a method of producing doubt; and regarded it as dangerous to the principles of the young. Plato carefully obviates such a misrepresentation of his proceeding, and guards his method from being confounded with that of the Sophists. The Sophists taught the art of exciting doubts on every subject; a mere effort of gladiatorial skill. They professed to make men apt to cavil and dispute on any given subject.[2] All principles, according to them, were equally stable; all were equally open to be impugned. They, therefore, did not care how they unsettled the minds of men, if their skill could only find materials on which to exercise itself. In Plato's hands, however, the awakening of doubt has for its object, to remove the unstable ground on which opinions may happen to be rested, and to lead to more settled convictions. With him it is exalted into a regular discipline of the mind. With the Sophists, it was perverted to strengthen that universal scepticism in which their whole teaching was based. So strictly does Plato confine the application of his method to the single purpose of investigating the truth, that he strongly objects to the use of it as a mere exercise of ingenuity; lest the young, led on by the pleasure of refuting and perplexing others, should think, at last, that there were no real distinctions of right and wrong.

Plato seems the more anxious to distinguish his method of inquiry from that of the Sophists, as his method did in some measure resemble theirs. It was inquisitive on every subject, as theirs was. It did superficially appear to be nothing but questioning, and doubting, and cavilling. It did appeal to the reason of every man, and oblige him to see how he could defend his opinions. And on this very ground Socrates had been attacked: for he was accused of corrupting the young, by making them "doubt," ἀπορειν ποιουντα.[3] Plato fully admits that this practice, as pursued by the Sophists, was dangerous to the principles of the young. In fact, he observes it would be even better to suffer them to remain under the guidance of some principles which, though not true, served as restraints on their passions, than to remove everything from their minds, and leave no check whatever to licentious indulgence. By a beautiful illustration, he compares the effect produced by the sophistical method, to the case of a child brought up amidst wealth, and luxury, and high connections, and the society of flatterers, but in ignorance as to his real parentage. Suppose, he observes, such a person to come to know that those, whom he has hitherto believed to be his parents, are not so, and at the same time not to know who his real parents are. It is clear, that whilst in his state of ignorance concerning his supposed parents, he would respect and attend to them more than to his flatterers; but on finding out his mistake, unless he were of a superior character, such as is rarely met with, he would attend to his flatterers more than to those whom he once supposed to be his parents. So would it be, then, he shews, with one who should find out that the popular principles of morals in which he had been trained, were not the truth, without arriving, at the same time, at the real truth. He would no longer be controlled by those moral principles of which he had discovered the falsehood; but having nothing to substitute in their place, he would give way afterwards, without reserve, to the seductions of pleasures, the flatterers, whose blandishments he had before in some measure resisted.[4] In opposition to such a system of cavilling, Plato holds an even course between the scepticism which merely doubts about everything, and the dogmatism which pronounces on everything without examination.

The method by which he accomplishes his object, carried out to the fulness of a regular system and discipline of the mind, is, what he calls by a term conveying to a Greek ear its colloquial origin and application, DIALECTIC. As contrasted with the spurious method of the Sophists, or the method of contradicting on every subject, and involving the mind in endless perplexity, it was the true art of Discussion. As contrasted with the mere wisdom of opinion, δοξοσοφια, which the Sophists inculcated, it was philosophy, real science, or knowledge of the truth. The method of his philosophy, and his philosophy itself, thus run up into one, and coincide under the common name of Dialectic.[5]

To trace the manner in which this coincidence was effected, will lead us to a perception of the true character of Plato's philosophy, as a system mediating between the dogmatism of the sciolist on the one hand, and the scepticism of the disputant on the other.

The hypothesis, we observe, on which he founded the whole of his proceeding, was the fallaciousness of Opinion; the Sophists, on the contrary, assuming the truth of Opinion

Plato's Writings and Philosophy.

universally. Whilst to the Sophists every opinion served as a ground of argument, and for them there was no need to look beyond the *apparent;* it was necessary for Plato, to seek for some Criterion of Truth out of the region of mere Opinion. Commencing with denying the sufficiency of what metaphysicians call subjective truth, or the assumption that whatever is perceived by the mind is true, because it is so perceived; he had to search after objective truth, truth independent of the mind of man, and exempt from the contingencies and variations of human judgment, as a foundation of his system of knowledge.

The hypothesis, accordingly, of the fallaciousness of Opinion from which his Method set out, involved a corresponding hypothesis in philosophy of the fallaciousness of the senses. It is the joint application of these two fundamental principles that combines his Method and his Philosophy in one master-science of DIALECTIC. Opinion, according to him, is the kind of knowledge derived from the information of the senses, and is therefore no proper knowledge at all, but mere belief or persuasion, πιστις; whereas true knowledge is founded on that which is purely apprehended by the intellect, without any intervention whatever of the senses. Dialectic, as it is philosophy, is conversant about that which IS, or which has BEING, as contrasted with presentations to the senses, which have only the semblance of Being; as it is a method, it investigates the reason, or account of the Being of everything;—the account of everything as it IS, and not as it APPEARS; not being satisfied, like its sophistical counterpart, with opinions of which no account can be given, but bringing all to the test of exact argument and definition.

In order, therefore, to give his Method a firm basis, and his philosophy a distinct object, it was required, that he should establish a sound theory of Being, or, in other words, a sure Criterion of Truth. Such, then, was his celebrated Theory of IDEAS.

There are four distinct views embraced in this theory as it is developed by Plato; four phases, as it were, under which it is presented.

I. The first, and most strictly Platonic view of it, according to what we have already stated, is in its connection with logical science. None of the great philosophers before Plato; none, that is, of those who had speculated on the universe at large, as Thales, Pythagoras, Heraclitus, Parmenides, Anaxagoras, were conversant with logical science. Zeno the Eleatic, and Euclid of Megara, were known indeed as dialecticians. But the kind of logical science which they professed, was a rude and imperfect art, consisting chiefly in the knowledge and use of particular fallacies, and not founded in any deep study of the nature of thought and reasoning. They were, besides, mere dialecticians, rather than philosophers in the most extended sense of the term. Plato's mind, however, while it was engaged in logical studies, was also no less intent on the investigation of the first principles of all things. And, as has been often observed in other cases, the favourite study of his mind gave its complexion to his theory of first principles, or doctrine of Ideas.

The term "Idea" does not indeed convey to the understanding of a modern any notion of a connection of the theory with logical science. In our acceptation, it belongs exclusively to metaphysics. But in Plato's view there was no separation of the two branches of logic and metaphysics. Both were closely united in the one science to which he gave the name of Dialectic, and which was accordingly at once a science of the internal reason,—that is, of the processes of the mind in its silent speculation on things; and of the external reason,—that is, of the processes of the mind in communicating its speculations to others in words. The terms, therefore, belonging to the one process, are indiscriminately applied to the other. Thus, to "give a reason" of the being of a thing, διδοναι λογον τῆς οὐσιας, was equivalent to a scientific view of it; and the word λογος denoted at once the terms of language by which that reason was expressed, and the reason itself as it existed in the mind. Thus, too, the word ἰδεαι, or ideas, was only a little varied from the logical term εἰδη, or species, which indeed is sometimes substituted for it in the phraseology of Plato. The simplicity, accordingly, and invariableness, and universality, which belong to terms denoting the agreement of a variety of objects in certain characteristics, were transferred to supposed counterparts in the mind itself, or to the notions represented by the terms which are the name of the species. Hence the idea, or *eidos,* was conceived to be, not simply a result of a process of the mind, but something *in* the mind, and as having a being independent of the mind itself. As the species expressed in words was universal, so its counterpart in the mind was the universal nature in which the individuals to which it referred, participated. In that, the mind, perplexed by the variety and anomaly of individual objects, found an invariable sameness. In the contemplation of it, the mind no longer wavered and doubted, but obtained a fixedness of view. The idea, or species, therefore, was to be explored and reached in order to a just theory of everything, and was in itself that theory.

Plato's Writings and Philosophy.

Further, as there is a relative classification of objects by means of words; some standing for characteristics common to a greater number of objects, whilst others stand for characteristics of only some out of that number; this property of words was in like manner conceived to have its counterpart in the mind. A graduated series of species was supposed to exist, first in the mind, and then independent of the mind, by means of which, as by steps, the mind might rise to the highest species, the ultimate idea itself, in which all others were comprehended. And hence there was no real perfect science but that which penetrated to this ultimate nature or being; and all other ideas, or theories, were truly scientific only as they participated in this.

This notion of "participation" of the ideas, was a still further application of logical language to the business of philosophy in general. For, as the several particulars belonging to a species all possess those characteristics which constitute their species, as well as those which connect them with a higher species or genus of which they are the species, their logical description is made up of an enumeration of those characteristics, together with the name of the higher class or genus under which the whole species is included. The higher class is an ingredient in the specification of a lower; or, conversely, a lower class participates in a higher. So Plato considered everything in the universe, as being what it is, by a "participation" of the Ideas; and consequently, that to explore its nature we must ascertain the idea which thus constitutes it. The Pythagoreans before him spoke of things as existing by "assimilation" to the essential being. Plato's logical views occasioned this change of phraseology; for he varied only the term, as Aristotle observes, whilst he followed the Pythagoreans as masters in the fundamental conception of his theory.[1] Aristotle, indeed, whilst he assigns the logical studies of Plato as the occasion of the form of the ideal theory, more particularly accounts for the theory, from Plato's observation of the importance of definitions in the ethical discussions of Socrates. Plato found how effectual an instrument Definition had been in the hands of Socrates in silencing the impertinencies of false opinion on moral subjects. As it had brought moral questions to an issue, so it might be applied, he thought, generally, as a stay to the extravagancies of opinion on all subjects whatever. Accordingly he had only to generalize the principle of definitions, and the result was the theory of

Ideas, or the universal science of reasons, and ultimate criterion of all truth.

To understand, however, rightly how Plato was led by logical considerations to his theory of Ideas, we should observe more particularly what his view was of the nature of logic. We should greatly misapprehend him if we supposed that he had that notion of the science which has prevailed since the systematic exposition of it by Aristotle. As it was conceived by Plato, it answered strictly to its original name of dialectic, rather than to that of logic; being the art of discussion, or the art of drawing forth the truth from the mind by questioning, rather than the art of deducing consequences from given principles. It was a higher, more comprehensive science, than the art of Deduction. For it was conversant about the discovery and establishment of principles; whereas the logical science which is employed about Deduction, assumes the principles in order to speculate about their consequences. It left the latter inquiry to be pursued by subsequent research, whilst the more ambitious flight of those who first speculated on the nature of Discourse was directed to the discovery of truth. In Plato's hands it was an energetic reform of the quibbling shallow logic, which was as yet known and practised in the schools. This logic had no concern for truth, but only for victory and display. It consisted in a skill of wielding certain sophisms, known by familiar names in the schools, and founded on the equivocations of words. An appearance of truth being all that it aimed at, it did not exact of the student any consideration of the nature of things. It was enough that he could give the word reason, the mere logos, the symbol or counter. He was not taught to go beyond this legerdemain of language, or to search out the reason of the being of things, and correct the paralogisms involved in the use of words, by reference to the realities represented by them. This sophistical method affected indeed to be a didactic art; to instruct and furnish the mind with principles applicable to every subject of discussion. It considered, forsooth, language as an universal science of nature already constructed; and, proceeding on this supposition, professed to enable the student to apply the wisdom already embodied in language, to the purpose of appearing wise himself, and imparting to others the same apparent wisdom. But going no further than this, it ended in mere δοξα, mere opinion. It produced, that is, in the result, only a wavering state of mind, subject to be changed by every new impression of opposite arguments, and imparted no steady knowledge.

It was a great reform, then, which Plato undertook, in following up the example proposed in the conversations of Socrates, and instituting a proper science of Dialectic, a science of the reason of the being of things. It was a change from an empirical system, a vain art of words, to a scientific method or investigation of the reasons themselves, on which an instructive use of words must be founded.

For, we must observe, it was still a science of words which he teaches as the true logic or dialectic. It had throughout a reference to discussion. Still it was a real science as compared with the verbal and technical logic of his predecessors. Though it was a science of words, it had for its object the determination of such words as should fully correspond to their intention as symbols, in characterizing the proper being of the thing denoted. These reasons of the being of things, the λογοι της ουσιας, were the Ideas.

His logical method, accordingly, was an analytical, inductive method. Setting out on the assumption of the erroneousness of opinion as such, it examines hypothesis after hypothesis on each subject proposed for discussion, rejecting and excluding, as it proceeds, everything irrelevant. The scrutiny instituted consists in searching for the grounds of contradiction with regard to each opinion, and shewing that opposite views on point after point in the matter discussed, are at least as tenable as the assumptions contained in the given opinion or hypothesis. Hence it consists almost entirely of refutation, or what both he and Aristotle denominate *elenchus*, a process of reasoning by which the contradictory of a given conclusion is inferred.

A method of this kind was calculated fully to put to the test every unsound opinion. It collected everything that could be said either for or against a given opinion. It made the maintainer of it state on what grounds he maintained it, what consequences followed from it; and either forced him to self-contradiction in his defence of it, or obliged him to modify it according to the requisitions of the argument. And the result was, that whatever stood its ground after this complete sifting of the question, might be regarded as stable truth. When refutation had done its utmost, and all the points of difficulty and objection had been fully brought out, the dialectical process had accomplished its purpose; and the affirmative which remained after this discussion might be regarded as setting forth the truth of the question under consideration. For everything connected with it, and yet not founded in the truth of things, was then removed. And the result therefore might be accepted as a simple truth of being, an object which the eye of the intellect might steadily contemplate.

The process throughout corresponds with the process of investigation in modern philosophy. Only we must conceive the dialectical investigation of Plato as nothing more than an admirable scheme for clearing a question of everything foreign to it; whilst the latter draws out the true law of nature from the promiscuous assemblage of phenomena under which it is presented to observation, and concealed until analysis has done its work on the mass. The nomenclature of the two methods varies accordingly. Argument is the instrument of the former; experiment that of the latter. Refutation is the primary business of the former; rejection and exclusion of irrelevant phenomena that of the latter. Definitions of words, as they are signs of the being of things, are the result of the former; whilst the latter developes laws of nature.

Both processes are carried on by Interrogation. But whereas the analysis which investigates a law of nature proceeds by interrogation of nature, the analysis of Plato's dialectic proceeds by interrogation of the mind, in order to discover the true being or idea of the thing discussed. Therefore it was that Socrates called his art, in his own playful manner, μαιευμα, a kind of midwifery;[1] a delivering of the mind of the notions with which it was pregnant. Thus the dialectic of Plato, being entirely directed to observation on the mind, and not to external nature, takes the state of knowledge as it exists in the mind for the ground of its proceeding. It deals with things; that is, as they exist in the forms of thought; going, as Plato says, "from species to species, until it arrives at the principle of all things,"[2] and following throughout the steps by which the mind advances in obtaining an exact view of any object of its contemplation. It is, in fact, the true thought spoken out. The process of thinking by which it is attained, is the dialectical process of interrogation. The decision of the mind when its conviction is settled, is the dialectical conclusion.[3]

The chief logical instrument employed in this method is division. The being able to divide according to genera, and not to consider the same species as different, nor a different one as the same, is stated to belong especially to dialectical science.[4] In searching out the true definition of the being of a thing, this portion of the internal process of the mind would naturally strike the attention. General ideas being founded on general resemblances of objects, the first step towards a more distinct idea of an object is to see that the generalization is complete; that it neither excludes nor includes any objects which it ought not to exclude or include. The true idea of any object would be that which characterized every object belonging to the idea, and none other. The analysis accordingly pursued by Plato is conversant about Division, using the induction of particulars in subordination to this.[1] We find, indeed, a constant use of Induction by Plato, after the manner of Socrates. But it is always in reference to the main purpose of determining, not a general fact, but the dominant Idea in every object of thought.

[1] *Theætet.*

[2] *Rep.* vi. p. 124.

[3] *Theætet.* p. 151.

[4] *Soph.* p. 274.

At the same time, we may observe, the Dialectic of Plato is truly a method of investigation, though it does not penetrate to the depth of the modern analysis. It employed deductive reasonings; but these were not essential parts of its method; since the whole was a process of ascent to the theory of the Ideas.

Afterwards, indeed, Dialectic approximated to what is now commonly understood by Logic. The transition was first to the consideration of it as a method of drawing out the probable conclusions deducible from given premises. This was natural. For in Plato's method every opinion was admitted as an hypothesis to be examined, in order to rejecting the falsehood and eliciting the truth that might be contained in it; and so far his Dialectic might be regarded as a speculation on probabilities. This transition prepared the way for a further one, when Dialectic became strictly the science of Deduction. Attention would be drawn more and more to the use of words as instruments of reasoning, when Dialectic was once exalted into the rank of a science.

The progress seems to be this. The science being cultivated primarily with a view to discussion, the importance of language in order to reasoning could not fail, from the first direction of the mind in this channel, to strike the philosophical observer. The phenomena of sophistical argument would suggest the necessity of inquiry into words as they are employed in reasoning. Philosophers, accordingly, would be led to examine into the nature of words considered as signs and representatives of thought. Thus they would proceed to arrange words into classes, according to their import in this respect. Thus would be obtained that great division of words into those that denote an individual alone, and those that stand both for many and for one, or into singular and common;—the fundamental principle of logic properly so called, or of logic as the science is now considered. The use of Division and Definition would soon appear. These processes, indeed, would be naturally discovered in the very prosecution of discussions addressed to the refutation of false opinions and popular fallacies. The early dialectics, accordingly, abounded in the use of them.[2] Afterwards, as the analytical power of language came to be more particularly observed, the connections of words in propositions and arguments would attract speculation. The possibility of exhibiting any given proposition or argument under abstract formulæ, in which unmeaning symbols were substituted for the terms themselves of the proposition or argument, would at length be discovered. Thus in the result would be erected a formal science of logic, in which language would be considered as an artificial system of signs, and the validity of arguments would be explored, independently of the subject-matter about which they happen to be conversant.

When Plato, however, drew his Theory of Ideas from the logical speculations in which his mind was engaged, there was no such system as that now found in treatises of logic. There are the materials in the writings of Plato for constructing a method of dialectic, such as the science presented itself to his view; but that method remains, even to this day, to be fully explored and stated. It is clear that he had such a system, and that his writings proceed on regular method; though he has nowhere accurately sketched it, and perhaps never even proposed it to himself in the form of a system. His thoughts were engaged in this, as in other subjects, in giving the great outlines of his philosophy. It was enough for him to have seized the bearings of logical truth on all truth; and to this general view of the science he has made everything secondary and subservient.

II. The next aspect under which the Theory of Ideas should be considered, is that in which it sums up and measures the infinites of the sensible world. In this point of view it more immediately represented its Pythagorean prototype, than under its logical aspect. It is in reference to this intention of the theory that Aristotle objects, that whilst it professes to give the account of things, it introduces an additional number of objects in the Ideas themselves; an absurdity, he observes, like that of attempting to facilitate a calculation by adding to the numbers to be calculated.[3] It was, accordingly, an endeavour to reckon up the individuals of the universe, and exhibit their sum in one statement. As Plato's logical speculations gave their colour to his whole philosophy, so the devotion of the Pythagoreans to mathematics led them to form a mathematical theory of the universe. The universal nature of number gave them the ground for this application of their peculiar studies. For all things are in number; and there is nothing from which the notion of number may not be abstracted. That number, then, which alone measures all other numbers,—Unity,—would be regarded as the common measure of all things. And thus the philosophy of the universe would be reduced to a system of calculation; and the infinity of existing things summed up in definite proportions of numbers. The Greek word *logos*, whilst it combined in it the notions of "word" and "reason," also further combined that of "ratio," and reasoning and calculating were expressed by the one term λογιζεσθαι. This marks the connected trains of thought by which the arithmetical theory of the Pythagoreans was formed. The effects of this combination of thought are seen, not only in the fundamental conception of the theory, but in our ordinary phraseology on the subject of reasoning even at this day; as, for example, in our use of the word "Term,"—that is, "limit," or "boundary,"—for words, not only in their logical signification, but even in their familiar use.[4]

It appears to have struck the mind of Plato that the theory of the Pythagoreans was not sufficiently comprehensive, or even ultimate, as an account of the Being of things. The simplicity of Number did not adequately explain the great variety of natures found in the universe; and though the science of Arithmetic held almost the highest place in his scale of knowledge, on account of its abstract nature, and its leading to the consideration of Being, apart from the changeable objects of sense; he still viewed it as practically implicated with the physical sciences, and, as such, therefore, not strictly and exclusively conversant about Being. In like manner, the science of Geometry, though purer than the physical sciences, as being conversant only about abstract magnitudes, is excluded from the highest place. Geometry, no less than Arithmetic, might seem to be simply an intellectual contemplation; since, though it employs visible figures in its demonstrations, the demonstrations do not refer to these, but to the abstract notions which the diagrams represent. Yet Geometry, as it assumes its principles, and its truths consequently depend on assumptions which in themselves demand evidence, cannot, he observes, rank as perfect intelligence.

---

[1] Πολυ δε μαλιστα και πρῶτον την μεθοδον ταυτην τιμᾶν, τοῦ κατ᾽ εἰδη δυνατον εἶναι διαιρειν. (*Polit.* p. 66.)

[2] Τουτων δη ἐγωγε αὐτος τε ἐραστης, ὦ Φαιδρε, τῶν διαιρεσεων και συναγωγων, ἱν᾽ οἷοστε ῷ λεγειν τε και φρονεῖν· ἐαν τε τινα ἄλλον ἡγησωμαι δυνατον εἰς ἑν και ἐπι πολλα πεφυκοτα ὁρᾶν, τοῦτον διωκω, κατοπισθε μετ᾽ ἰχνιον ὥστε θεοῖο· και μεντοι και τους δυναμενους αὐτο δρᾶν, εἰ μεν ὀρθως ἡ μη προσαγορευω, θεος οἶδε· καλῶ δε οὖν μεχρι τουδε διαλεκτικους. (*Phædr.* pp. 362, 363.) Plato appears to have been the author of a work "On Divisions," not now extant.

[3] Ὥσπερ εἰ τις ἀριθμῆσαι βουλομενος, ἐλαττονων μεν ὀντων, οἰοιτο μη δυνησεσθαι, πλειω δε ποιησας ἀριθμοιη. (Aristot. *Metaph.* i. 7.)

[4] Hobbes uses the mathematical phraseology throughout. Reasoning, with him, is "reckoning," and words are "counters." (*Leviathan*, i. 4, *et alib.*

Perfect intelligence, *νοησις*, implies an absolute stay to the thought; something beyond which no further inquiry can be made, which may be seen as it were by the mind's eye immediately in itself. And such an object only is furnished by the Idea. Though, accordingly, Plato thus carried his theory beyond that of the Pythagoreans, we find him still cherishing the Pythagorean doctrine of Number, by assigning to it the second place in his scale of knowledge, and only barely distinguishing it, in regard to scientific value, from his own Theory of Ideas.[1]

When we come indeed to look more closely into his theory, the mathematical approximation will distinctly appear. The ideas are the finite, applied to the infinite of the sensible world, and thus producing measure and proportion in the universe.[2] The physical sciences, as, for example, astronomy and music, are not truly scientific, because, addressing themselves to what is passing before the senses in the world, they do not consider the immoveable beings themselves, which are only imperfectly represented in the observed physical movements. The astronomer computes the actual velocities of the heavenly bodies; the musician counts the intervals of sounds. But neither of these is intent on the real beings, the Ideas themselves of velocity and of harmony. We can discern in such language as this, a mathematical basis of thought. Perpetual variations, as contemplated in their inconstancy, admit of no calculation. To estimate them, we must find the limit to which they continually approximate, and we thus, as it were, reduce to fixed order the apparent disorder and irregularity, and see the variable in its ultimate form of invariableness. This notion is not fully developed by Plato. But it is conveyed in his doctrine of a twofold class of sciences, under the same names; a popular astronomy, for example, and an higher astronomy; a popular music, and an higher music; the latter of which are sciences of the invariable and the finite, and run up into his Theory of Ideas.[3]

III. The third phasis of the Theory is that in which it is a philosophy of Being, in opposition to the mere knowledge of sensible phenomena. According to the school of Heraclitus, the sensible world was ever flowing, ever in a state of becoming or incipiency; being a mere development of successive phenomena, displacing each other without cessation. As duration is no positive existence as a whole, but is made up of an infinite number of moments, each of which is gone as the succeeding moment appears; so was it asserted generally in the doctrine of that school, that every object in the universe was a mere collection of successive phenomena. Of nothing could it be affirmed that it IS. The very sensations, no less than the objects of them, were in constant production; being the momentary, ever-varying results of the concourse of agent and patient. Colour, for example, as the object, and sight of the colour in the eye as the sensation, are momentary relations simultaneously produced by something that acts in the coloured object at the moment, on something that receives the impression in the eye.[4] This doctrine resolved all knowledge into sensation, and (which was equivalent to this) made "man the measure of all things," according to the celebrated enunciation of Protagoras.

Plato saw, that if these views were admitted as an account of the universe, his whole dialectic must fall to the ground. It would be nothing but miserable trifling to try to call forth those reasons of things which he conceived to be in the mind, if knowledge were of this fluctuating character.[5] There could not, in fact, be then any such reasons. There was nothing stable, nothing that remained in the mind, to serve as the standing criterion of true and false opinions. There would be no distinguishing whether all that passed in life were not a dream, or whether the occurrences in dreams were not rather the realities.[6] Some sure criterion was therefore wanted, to which the phenomena of sensation might be referred. The theory of Ideas, as a theory of Being, furnished this.

Plato admitted, accordingly, the perpetual flux of sensations and their objects, as taught by Heraclitus, whilst he refuted the sophistical extravagancies into which the doctrine had been carried. Granting, therefore, that there was no test of truth or falsehood in the sensations themselves, he points out, that the ground of fallaciousness is in the judgments formed by the mind concerning the impressions of the senses. The soul is endued with a common power of perception, to which the reports of the different senses are referred, and by means of which the mind is enabled to compare past and present sensations of the same kind, as also different sensations with one another. It is in the conclusions then formed on these comparisons that we are to seek for knowledge; or in the purely mental processes, abandoning altogether the mere informations of sense.[7]

He was led, accordingly, to examine these processes of the mind, in order to discover the grounds of truth and knowledge. He observed, that when the mind compares two sensations, and decides on their similarity or difference, there is always some ground on which that judgment is made. When, for instance, it decides on the equality of two things, there is a standard to which they are referred, the general notion of equality itself, which serves as a middle term for testing the equality of the two things compared. In like manner, there is always, whenever a comparison is made by the mind, some general principle, which is the medium of the comparison. And this is a principle not in any way produced by the sensations; for it is evidently prior to them, and independent of them; being appealed to by the mind as a criterion of them. This general principle, then, is in every instance the Idea; and not being formed by the sensations, it is not subject to their variableness. It remains unmoved, and the same, amidst the flow of the sensations, or of the objects of the sensations;—the standing criterion of all the judgments of the mind to which it applies.[8]

Hence we may see the peculiar meaning of the term "Idea" in Plato's philosophy. It consists in its contrast with the objects of sensation. The latter never attain to any definite perfect form—to any clear outline, as it were, to

Plato's Writings and Philosophy.

Plato's Writings and Philosophy.

the eye. They flow and have vanished before they could attain to such form; since, in the very succeeding one another, they not only pass away, but undergo alteration. But the standard to which they are referred in the mind, is a positive defined shade, or form, or species, simple and uniform, analogous to an object of sight of which we can clearly trace the whole outline by the eye.[1] For the like reason, the term *exemplar*, παραδειγμα, is also applied to denote the Idea. As the one perfect standard to which all the reports of the senses are referred, it appears in the light of a pattern, to which they would be conformed, but for that incessant mutability which necessarily belongs to them. This, however, was rather the Pythagorean view of general principles than the Platonic, though Plato himself not unfrequently recurs to it.

Plato, at the same time, in thus constituting Ideas the sole absolute criteria of real existence, did not intend to deny all reality whatever to conclusions drawn from our sensible experience, such as those of the physical sciences. But he means, in the first place, to shew the delusive character of all informations of sense which are not corrected by the internal reason of the mind. In the next place, his design is to point out the inferior knowledge which every other kind of evidence conveys, but that which is drawn from the intuitive perceptions of the mind. The mere informations of sense, he teaches, are only a knowledge of semblances or idols, εἰκασια, conjecture founded on mere images of the truth. He describes this kind of knowledge by an admirable illustration from a supposed case of men placed in a long cavern, with their bodies so chained from infancy, that they can only look before them, whilst the light of a fire from behind casts on the side opposite to them, the shadows of vessels, and statues of stone and wood, carried along a track leading upwards from the cavern by persons who are themselves concealed by a wall, like the exhibitors of puppets. As men so circumstanced would see nothing of themselves, and of each other, or of the things thus carried along, but the shadows, they would mistake the shadows for the realities; they would speak of the shadows as if these were the things; and if any voice was heard from the persons carrying along the figures, they would think the sounds proceeded from the passing shadow.[2] Just like this, he declares, is the influence of education in the lower world of sense on the minds of men. They must be carried up from this cavern, in which they see everything only by an artificial light, to the light of the sun itself, to the region of Ideas, where alone objects are seen as they are in themselves.

As to the knowledge conveyed by the physical sciences, neither is this properly science. It amounts only, as he states it, to belief or opinion. These are less intellectual than the mathematical sciences, because they are conversant about human opinions and desires, or about the production and composition of things, or about the means of sustaining things produced and compounded.[3] They are therefore as unstable as the things about which they are. But they are still not devoid of evidence, so far as they collect the real informations of the senses, and do not learn from mere shadows. This is implied in his calling such knowledge belief, and distinguishing it from conjecture; though he is rigid in preserving the exclusive prerogative of Truth to the knowledge of the Ideas.

The evidence of Experience was necessarily slighted in such a philosophy, and condemned as insufficient for the discovery of truth. For what is Experience but the memory of several similar previous informations of sense, combined into one general conclusion? And though Aristotle allows that such a general conclusion, in which the mind acquiesces, might be regarded as scientific,[4] this could not be admitted by a philosopher who placed the objects of sensation out of the pale of Being. It was not enough for Plato's system to answer in favour of the scientific value of Experience, that though this and that particular instance of an information of sense had no immoveable truth in it, yet, from the observation of a number of similar instances, a general uniformity might be inferred, and an immoveable general principle established. He would grant that generalization was a corrective of experience. For this he did when he granted some importance to the arts in education, and for the purposes of life. But truth with him must be *universal*, not simply general: it must be that which is always the same, not simply that which is for the most part. And the highest degree of the evidence of experience, even that which amounts to what is called moral certainty, falls short of this absolute universality. It might be urged, for example, that though what was sweet to one person and at one time, might be bitter to another person and at another time; and though what seemed the same sensation of sweet, was not in fact the same at two successive moments, but a reproduction; still it was possible, by combining recollections of many similar instances, to form a general notion which should adequately characterize that sensation. Still Plato would say, this was only belief or opinion, and not science. The object of science must be such as cannot be otherwise: it must be absolutely one and the same permanent being: you must altogether quit the stream of the world of sense, and land on the rock of unchangeable eternal Being.

Thus Rhetoric is strongly reprobated by Plato, on the very ground on which it is systematically taught by Aristotle, of its being nothing more than an instrument of persuasion, or an art speculating on the means of persuasion. Much of his invective indeed derives its point from its application to the servile rhetoricians of his day. Still we find him condemning Rhetoric on the abstract ground of its having no higher view than persuasion. In the modern view of the subject, as in Aristotle's, Rhetoric is a real science, so far as it is framed on just conclusions respecting those modes of speaking, or writing, which excite interest and produce conviction. With Plato it is mere quackery; and for this reason, that it is founded on experience of what persuades, being only an ἐμπειρια or τριβη, a knack acquired by experience and converse with the world; an accomplishment, learned by practice, without any real knowledge, in flattering the passions of men. He in fact regarded Experience as corresponding with what we call empiricism; contrasting it with the conclusions of abstract reason, as we contrast an illiterate and unscientific use of experience with that of the philosopher.[5]

Looking to that sort of experience on which the popular teaching of the Sophists was founded, Plato, we should say, was fully justified in his condemnation of the experimental method of his day. It was in truth mere quackery. It was content with shadows and images of the truth, and entirely directed to *producing* a desired effect, without caring for the absolute truth;—a shallow philosophy of sensation, not founded in the nature of things. He had thus to contend against a system, which distorted that criterion of truth, which man has in himself, by the right use of his reason conjointly with his experience, to the undermining of all truth and reality. This empirical system was the crying evil of those times.

It had infected politics, and education, and private intercourse, as well as philosophy. In opposition to it, he had to take up an antithetical position; to call in question the existing acceptation and use of the human criterion of truth; to limit it within its proper bounds, and guard against its perversion. Accordingly the whole stress of his philosophy is on this point. It is a perpetual polemic against the sophistical principle, that "man is the measure of all things."[1] This amply accounts for his disparaging so much as he does, the scientific value of Experience, and insisting on the necessity of the existence of higher principles than those of Experience, in order that the mind may duly receive and appreciate the information of sense. He taught men, at any rate, to perceive that the popular notion of that evidence of truth which man has in his own nature was false and deceptive, and that in all judgments and reasonings there is also something more than is merely of man.

IV. The fourth leading point of view under which the Theory of Ideas remains to be considered, is its aspect as it is a theory of the Cause of the universe. Under this aspect it is identified with the speculation into the Chief Good. Here it is an account at once of the first principle of motion, and of the end to which all things tend as their perfection and ultimate good. According to Plato, there was no other cause worthy of the name, or which really accounted for the phenomena of the universe, but "The Good," or, as it is technically called, the Final Cause. The early speculations of philosophers had been chiefly directed to the material phenomena of the universe, and had attempted to account for them in a rude manner, by referring them to some one or more of the material elements. Some indeed had introduced also moral influences into their theory. The Pythagoreans combined with their speculation of the mysterious Unity, the notion of Love as the one-making principle. The Ionic school, however, appears to have led the opinion of philosophers in regard to the cause of the universe at the time of Plato. And though Anaxagoras asserted the ascendancy of mind, he had lost sight of his great theory in the explanations from material causes, to which he descended in the completion of his system. Socrates began a strenuous opposition to the physical philosophers. Plato carried on that opposition, and, blending the familiar ethics of Socrates with the moral and theological mysticism of the Pythagoreans, established the Final Cause or theory of "the Good," as supreme over the domain of science.

Anaxagoras had certainly prepared the way for the theory. Plato took up his doctrine of a Divine Intelligence, and gave it that development which, as it had been taught by Anaxagoras himself, it yet waited to receive. It was but a vain theory of a Supreme Mind (sublime and important as the simple enunciation of the great truth was), which did not also exhibit the Supreme Mind as operating in the universe by design, and as diffusing the energy of its intelligence and goodness, as well as of its power, throughout its operations.

The Supreme Mind, therefore, according to Plato, must be conceived, as exemplifying the attributes of its own nature in the works which have proceeded from it. If it be granted that there is a Supreme Mind, that must be the true measure of all things in the universe. All things must have been framed according to the scheme which such a mind would contemplate in their production. As intelligence, it cannot be regarded but as working for some object, ἑνεκα του; for by this is intelligence distinguished from unintelligent force; and the only object to the supreme intelligence is the most perfect nature, which is itself. The pattern of its own perfections, therefore, must have been present to it, and in its design, in the construction of the universe. In other words, the Deity himself is not only the author of all things, but he has designed to exemplify in them his own attributes. The principle, accordingly, by which all true philosophy must hold, and which it must carry out into its speculations, is, that "God is the measure of all things."[2] And hence, whenever the proper being of any thing is to be explored, it must be studied in that light in which it is seen as a work of the Supreme Mind, designed after the pattern of the divine perfections. In such a contemplation, the theory of the Best is the view by which philosophy must be guided; for, in ancient philosophy, an object of intelligent aim, and good, are equivalent terms. The object at which the most perfect intelligence aims, must be, therefore, that which is best; and in tracing out, accordingly, the workings of the Divine Mind in the world, we must look for "the best" in everything. That notion of everything by which it is "best," is both its real nature, and the cause of its being produced.

But why is not everything, as it is actually seen, a work of "the best?" why is not good visibly impressed on everything as it stands forth to the view? why must we, in short, resort to the Idea of good, in order to ascertain its nature, instead of taking it simply as it appears?

The antagonist force of unreason in the nature of that which has body, and is apprehended by the senses, occasions all the imperfection and evil in the world, as the world actually exists. It subsisted already in the mass of disorder and confusion which the Divine intelligence, by its operation, had brought into order and regularity of motion; and it still subsists, though reduced into subordination to intelligence. It is overruled so as to minister to the designs of mind, but still impedes by its contrariety of nature the development of good in the world. And thus Plato says that it is impossible for evils to perish out of the world, for that there must ever exist a contrariety to good.[3] Evil pre-existed, and evil accordingly must be displaced by the presence of good; as contraries are displaced by contraries; and as all generation, or production, is carried on by a process from contrary to contrary. Thus, though evil retires before good in the world of generated things, evil still manifests itself in the very act of its retiring before good; and a perpetual opposition of good and evil remains. What we see, accordingly, in the world, is not the perfect accomplishment of good, but effort and tendency after good in all things. The effects of a struggle between reason and unreason are manifested, on the one hand, in the evanescent imperfect nature of all sensible things; and, on the other hand, in their constant renewing, or in that undying vigour with which they flow on, and are reproduced, and aim at a perfection beyond themselves.[4]

Though, therefore, the Divine Artificer has designed everything in the world for the best, they are not actually the best as they are presented to our senses. They are the best that such things can be, but they do not attain to the Idea of good, according to which they have been made. Time, for example, only imperfectly represents the divine eternity, which is its true Idea. In eternity there is no distinction of past, present, and future. But the bodily nature will not admit of this co-instantaneous development of the divine Idea. Existence is here broken up into successive moments; and these successive moments, marked by the periodic motions of the heavenly bodies, introduce the distinctions of number into the simple idea of duration.[5] Again, the velocities of the heavenly bodies, which are observed by the astronomer, must be conceived as very in-

adequate representatives of the "real velocities performed in the true number and true figures,"[1] which are the Ideas after which they have been established. Or, again, it is clear that the ideas of the good, and the just, and the honourable, and the beautiful, as they are seen in the world around us, are only imperfectly developed. Our thoughts are distracted by the contemplation of them in the world, by the multiplicity of forms under which they are apprehended by men, and it seems to the superficial glance as if there were no one perfect standard of each. At the same time, we are able to trace evident signs of such a standard, when we look thoughtfully at the course of things. We cannot doubt, on such examination, that these principles exist, and are working their way, and that the universe has been constructed after the pattern of them. But all that the most attentive study will disclose to us as actually observed, is *tendency* towards these principles—a "becoming" or incipiency of being.[2] We do not see their full effect, or what would be their effect, if the world were such as to give them free scope and exercise, and if the impressions of sense did not diversify and obscure the presentations of them to our minds. Must we not say, then, that if we formed our notions of these principles from the visible world, and the impressions of sense, that we must estimate them improperly? And must we not rather elevate our minds to the Ideas themselves, after which the universe has been constituted in its present order, and take our measures of them from the Divine Being, whose goodness, and truth, and beauty, they represent?

Thus did the Theory of Ideas serve as a moral explanation of the course of nature, and meet the demand of philosophy, by removing the perplexity of the mind on the contemplation of the apparent disorder of the world, and giving a firm stay to the thought in this direction. This apparent disorder has been the constant appeal of the atheist and the sceptic in all ages. And in Plato's time there was need, we find from several passages of his writings, of an answer on the part of philosophy to speculative objections on this ground. The Theory of Ideas supplied this answer. By the theory of a perfect model of good, imperfectly wrought out in the visible universe, the existence of evil was accounted for in some degree, and the eye of thought was enabled to see a chain of goodness, and beauty, and order, binding together the most untoward appearances of the moral world. As the Pythagoreans enchained these disjointed portions of the moral fabric, by supposing a fundamental Unity pervading the whole, and reducing the multiple and the unlimited to definite proportion—a sort of key-note, modulating the apparent discords of nature[3]—so Plato made the one moral good the all-pervading moderator of the system of the universe. The abstract notions, the genera, and the species, and the definitions, which dialectical science brought out by the aid of language, presented the materials for extending the moral view to other notions besides those strictly moral; and thus a theological and moral complexion was spread over the whole region of philosophy.

Ideas of evil were evidently excluded. "The good" could not be the cause of all things, but only of those that were well constituted; of evils it was causeless.[4] Evil, as we have seen, had no exemplar or pattern in the nature of the Author of the universe. It was a condition of that bodily nature on which the good was actively displayed. Evil arose from the nature of the "diverse"[5] inherent in body; that nature in body by which it was contradistinguished from the "sameness" belonging to the Ideas.

Plato's Writings and Philosophy.

In considering the Theory of Ideas under the different aspects which it presents, we have in fact taken a summary view of the whole of Plato's philosophy. This theory is the cardinal principle of the whole. The speculations on particular branches of philosophy are all included in this one theory, which binds them together and explains them. For when the mind had once risen to the contemplation of the Ideas, it needed no further helps from observation or study of nature to understand all knowledge. The mind was then in possession of the only true principles of knowledge; and to enter into the consideration of material and sensible phenomena, was only to return to the darkness and the dreams from which the eye of the intellect had been purified,—to quit the light of the sun for the cavern of shadows.

Accordingly, all his writings are devoted to the establishment of this theory. Proceeding on that notion of the importance of the theory which he inculcates, he bends every thought to this one point. No one science is set forth by him in detail; no one subject obtains with him a full and explicit consideration. All is resolved into its most abstract and general view, that the mind may be led to see the common principles of all truth; so intent is he throughout on his theory of Ideas, whatever may be his immediate subject of discussion. He assumes hypotheses, and examines them, and refutes them, in the way of argument, without pronouncing on either side of a particular question, as if indifferent about the establishment of any mere opinion, and desirous only of clearing his way for the perception of his theory.

But to place that theory in its full light, we should advert to the theories of Knowledge and of the Soul, which are intimately connected with it. These theories contain his account of the origin of the Ideas.

Knowledge, according to Plato, is Reminiscence, ’Αναμνησις, a recovery of forgotten truth, which had been possessed by the soul in a former state of existence. His dialectic professed to do nothing more than to lead the mind, by apt interrogation, to perceive the Truth for itself. It abandoned the attempt to communicate the Truth by didactic propositions. It only removed falsehood, and left the truth to its own course, to suggest itself to the mind, now disabused of its error and prejudice. It appealed to principles as certain criteria of truth, and yet confessed its inability to state those principles, and place them distinctly before the mind of the learner. They were simply referred to, as existing in every mind, whatever might be the peculiar opinions of the individual to whom the questions of the dialectician were addressed. How, then, could those principles have been acquired? No time in the present life could be pointed out when they first appeared in the mind. They are prior to the sensations, for the sensations are referred to them; and the sensations we have had from our birth. These standard principles, then, must have been acquired in a previous state of existence, and what is commonly called learning, is, in fact, Reminiscence; and to know, is, properly speaking, to remember.[6]

In proof of this account of the origin of the Ideas, Plato introduces Socrates making an experiment on the mind of an uneducated person. Socrates is represented putting a series of questions to a slave of Meno, and at length eliciting from the youth, after repeated correction of his errors, a right enunciation of a geometrical truth. Socrates then points triumphantly to the instance, and bids Meno observe how he had *taught* the youth nothing, but simply *interrogated* him as to his opinions, and the youth had himself recalled for himself the knowledge thus evidently existing in his mind.[1]

---

[1] *Repub.* vii. p. 158; also *Philebus*, p. 303.

[2] Παντα τα ἐν ταῖς αἰσθησεσιν ἐκεινου τε ὀρεγεται τοῦθ᾽ ὁ ἐστιν ἰσον και αἰτου ἐνδεεστερα ἐστιν (*Phæd.* 170); προθυμεῖται μεν παντα τα τοιαῦτα εἶναι οἷον ἐκεινο ἐστι δε αὐτοῦ φαυλοτερα (*Ibid.* 171). He goes on to say this applies to all subjects as well.

[3] Δεσμῶν δ᾽ ὁ καλλιστος, ὁς ἀν ἀυτον και τα ξυνδουμενα ὁτιμαλιστα ἐν ποιῆ, τοῦτο δε πεφυκεν ἀναλογια καλλιστα ἀποτελεῖν· ὁποταν γαρ ἀριθμῶν τριῶν, κ. τ. λ. (*Timæus*, p. 307.) The Pythagoreans were fond of describing moral ideas by terms drawn from mathematics and music. The good man, for example, was τετραγωνος ἀνευ ψογου; and the words πλημμελῶς, ἐμμελῶς, and the like, known from their philosophy, are familiarly used in a moral sense.

[4] ’Ουκ ἀρα παντων γε ἀιτιον το ἀγαθον, ἀλλα τῶν μεν ευ ἐχοντων ἀιτιον, τῶν δε κακῶν ἀναιτιον· (*Rep.* ii)

[5] Θατερου φυσις. (*Tim.* p. 315.)

[6] *Phædo*, pp. 166–174.

Again, in illustration of the same, Plato refers to instances of association. Often, on the sensation of a particular object, we are reminded of something else not present to us. On seeing a lyre, or a dress, which one whom we love has used, a thought occurs of the person to whom it belonged. So also, on seeing pictures of objects, persons and objects will be suggested to the mind, unlike as well as like to the objects in the picture. Or one of two friends, being presented to our view, we are reminded of the other who is absent.[2]

Now the instances here referred to, both those of association, and those of the self-teaching of the mind by the excitement of its reflection, are highly interesting and important in the history of the origin of ideas. But they do not prove the point for which Plato adduces them. The case of the slave interrogated by Socrates certainly shews, that there are principles in the understanding, which are not derived from external information, but which only wait to be developed by occasions apt to call them forth. And as to the instances of association, we can only say, it is an ultimate fact of our mental constitution, that particular objects serve to bring others before our thoughts. All such instances are illustrations of the fact, that the mind is not passive in its admission of truth, receiving knowledge simply as something infused in it from without; but that its knowledge is in great measure owing to its exertion of its faculties, and its bringing to bear on the instruction given its own intuitive convictions;—that consequently the excellence of all teaching consists, not so much in the positive mass of instruction conveyed, as in stirring up the mind to learn from itself.

The stress of Plato's argument in favour of the theory of Reminiscence, and of the previous existence of the Soul as a consequence of it, is laid, we find, on the ground of the priority of the ideas compared with the several particular sensations which are referred to them as criteria. But the priority which he here claims for the Ideas, is not, in fact, a precedence in the order of time, but of logic. In the process of reasoning, general principles are prior to, and more known than, the particulars which fall under them; because in possessing them we possess the particulars, and the particulars, as yet unknown, are known by deduction from them as already known. Thus we familiarly speak of a conclusion as *following* from the premises. Now, Plato appears to have transferred a priority of this kind to the Ideas, and then to have concluded their priority ABSOLUTELY, as principles existing in the mind independently of the occasions on which they are called forth. But to establish a theory of Reminiscence, it was further required to be shewn, that the ideas are prior in the order of *time*,—that we possess them antecedently to, and independently of, all experience. The instance which he has given of the way in which a mathematical conclusion is reached by the simple leading of the mind in the right track, is an instance of what has in modern philosophy been more properly called "Suggestion,"—not of Reminiscence. So far from being an instance of Reminiscence, it shews, on the contrary, that the general principles of the mind are developed *subsequently* to the particular occasions which suggest them. It shews, further, that these principles are in some way dependent on such occasions for their development, though not dependent on them for their truth and reality; for the mind accepts them as true, and as the criteria of all other truth, at the moment when they are presented to it. This, then, is what is really illustrated in Plato's instance in the *Meno*. Geometrical science is the best illustration of it, though it is seen also in all our judgments and reasonings; because the remote conclusions to which we are brought by the chain of demonstration in that science, from a few very simple definitions, present the fact most strikingly. Those conclusions are clearly far beyond the compass of the definitions themselves. They are strictly deduced from them, however, and with an irresistible cogency of argument. The wonder is accounted for, by the fact to which Plato has called our attention. The demonstration of the problem appeals in every step to the intuitive convictions of the mind. Ideas are suggested by which the statements at each point of the proof are tested; and we sanction the conclusion, because the process by which we arrive at it, has been approved throughout by clear principles of our own minds.

But though the theory of Reminiscence has not been satisfactorily made out by Plato, he has the merit of having distinctly noticed and marked, in speculating on the origin of the Ideas, a class of notions of which no previous account, as it seems, had been given. The philosophy of sensation had before his time chiefly engaged the attention of thinking men, whether of those of the Eleatic school, who made everything stationary, or of the Ionic, who made everything flow.[3] It had been carried into the extreme of refinement by the Sophists, its devotees, when Plato commenced his antagonist system. He found that this philosophy was too narrow a basis for the structure of science, and that it could not stand alone. He saw that it left altogether unexplored the perceptions of the mind itself, such, for example, as the notions of equality, identity, time, causation, right, &c.; and that these notions were, in truth, more important for the establishment of science, than those which had previously chiefly attracted the attention of philosophers. He applied himself accordingly to examine and characterize these principles. The main thing to be accomplished in such an inquiry, was to distinguish them accurately from the informations of sense; to shew that they were not included in, or in any way derived out of, the informations of sense, but developed by the workings of mind. This fact he has recorded in his theory of Reminiscence,—a term expressing the point of contrast in his method, to that of the empirical philosophers before him exclusively founded on sensation.

The truth and importance, accordingly, of Plato's Theory of Ideas, appear in this; that by that theory he laid a stable foundation of science, in the principles themselves of the human mind. His error is, that he carried that theory too far; that he included in it notions which are not part of the fundamental principles of the mind, and thus involved his theory in vagueness and paradox. The war of nominalism and realism is well known to every one, who has looked into the history of philosophy, or of theological opinion. This found its occasion in the wide generalization of the Ideal Theory. Had Plato restricted his theory to such notions as really exist in the mind; and had he not extended it, without discrimination, to those which belong to general terms, and which are purely notional; there would not have been that ground for controversy on the subject. As the case has been,—one class of disputants, looking to the generalizations of language, the genera and species of logic, took the nominalist view of the subject,—

---

[1] *Meno*, pp. 352–361.

[2] *Phædo*.

[3] Plato characterizes them; the one, as the τοῦ ὀντος στασιωται; the others, as ὁι ῥεοντες. *Theæt.*

imputing to the whole of the ideas the attribute of one portion of them ;—the other class of disputants, justly observing the reality of certain general principles, became the advocates of realism throughout. What has been already said on the dialectical origin of the theory, will sufficiently account for the confusion of two such dissimilar classes of principles in Plato's system.

How shall we wonder, therefore, that the great logical philosopher who followed him should find it necessary to combat the theory of Ideas in the undefined form in which it had been left by its author. As thus left, it stood in the way of those exact arrangements of the objects of thought which the rigorous method of Aristotle required, and introduced a class of existences for which he could find no place in his system.

Nor, further, will it be matter of wonder that controversies should have arisen in the schools respecting the nature of the Ideas ; such as, whether they subsisted by themselves, or were bodies, or actually separable from sensible things, or only separable from them in thought; or whether they were locally situated anywhere, or only in the Divine Mind. The establishing of the theory in its general form was the great business of Plato : it was enough for him to have projected it above the horizon of philosophy. Others would elaborate it after him with more or less skill. Various speculations would be raised concerning it ; and controversy would at length reduce it to more definite form, and a precision beyond the contemplation of its author.

But, however just and important the Ideal Theory is in its connection with metaphysical science, it is but too clear that it retarded the advancement of sound physical philosophy, by its substitution of final causes for physical, and consequently withdrawing attention entirely from the latter. It would follow, indeed, from the suspicion thrown over the informations of sense, and the undervaluing of experience, that physical science would be slighted under such a system of philosophy. But the dominion of the theory of Ideas would necessarily exclude any other consideration in order to the truth, but that of tendencies or final causes. No other view of nature, but that supplied by this theory, would be conceived to possess the stability which science demanded. Accordingly, hypotheses would occupy the place of investigation here. The philosopher would be speculating on what ought to be, instead of observing accurately what is ; and assuming *a priori* notions of " the best," in order to determine the law of physical facts. The principle, " that all things are constituted for the best," no doubt holds good in physics as well as in other studies of the divine workmanship ; but it is here the termination of inquiry, not the commencement. It may even be employed instrumentally in the process of inquiry, to lead the mind to a point to which investigation should be directed : and this it may effect in two ways. Either, from considering the good intended in the structure of some object, we may be led to see the parts of that structure in a way which discloses their real organization, and which we should otherwise not have observed ; or, from taking our view of an object, not as it is actually exhibited in inferior specimens, or in those states of it in which it is seen only in progress, or under distortion, but from the most perfect specimens,—those most answerable to a divine intention or tendency to the best,—we may judge what it *is*, by considering what it *would* or *should be*. But to lay down final causes as principles from which the truths of physics may be deduced, is, as Bacon says, to corrupt natural philosophy with theology, and to render it barren of all fruits.

Such, then, is the state of Plato's natural philosophy. In fact, though he asserts the importance of physics in his own sense of the term, the science has no place in his philosophy. He goes so far indeed as to say that no art can flourish apart from a knowledge of physical truth ; and he attributes the imperfect rhetoric of his day to its want of such a foundation.[1] But even whilst he imputes the superiority of Pericles as an orator to his studies under Anaxagoras,[2] he strongly objects to the system of that philosopher, as we have already seen, on account of his leaving out all consideration of final causes.

Accordingly, in the dialogue which fills up this department of his system, he speaks in the person of the Pythagorean, Timæus, and strictly follows the Pythagorean notions. The detail of this dialogue consists of a history of the order of the formation of the universe in all its parts ; commencing with an account of the universe at large, and the hierarchy of the heavens, and ending with a minute explanation of the structure of man, in regard to his moral and intellectual, as well as his physical powers. And here mathematical figures and proportions are the principles into which the composition and motions of all bodies are resolved. But the theory on which the whole speculation turns, and which gives the explanation of the phenomena, is the theory of " the Best." It is an account of Good operating throughout the universe, conforming everything to itself, and constraining the untoward nature of body to yield to its sovereign power. An intelligent and good author of all things is assumed ; and his order of proceeding is inferred from that which presents itself to our view as " the best." Thus the Father of the universe constructs it after the eternal unchanging pattern ; " for that is the noblest of generated things, and the best of causes." He formed by his immediate operation whatever is of eternal unchanging nature. Nothing, indeed, but himself, is immortal and indissoluble by its own nature ; but, good as he is, he can never be disposed to destroy what is good. And therefore the fabric of the universe and the celestial beings, the generated and visible divinities included in it (with the highest order of whom Plato's description identifies the luminaries of the heavens), subsist eternally, not of themselves, but by virtue of their participation of good."[3] Whatever is subject to death,—as the bodily nature of man and brutes,—being imperfect, is the work of the generated divinities, imitating the power of the Supreme. It is with these secondary Gods that he connects the popular mythology ; deriving from them the parentage of Saturn, and Jove, and the other objects of heathen worship ; and leaving the further account of their origin to be given by the current tradition. Thus the supreme God is described as the author of all good throughout the universe ; and where anything of evil or imperfection is, the agency of the subordinate powers, and the irrational nature of body, are interposed to guard him from imputation of evil.

Derived as his history of the universe evidently is from the early theogonies, it is very remarkable that it keeps clear altogether of the oriental dualism. There is but one active principle in his system of the universe, the principle of Good ; and nothing forms or moves but that only. " Let us not," indeed, he expressly says in another place, " conceive that there are any two gods, of contrary sentiments, causing the revolution of the universe."[4] He seems indeed to personify the irrational force of body, where he describes it under the name of *αναγκη*, necessity.[5] But he is evidently only speaking in metaphorical language here (that language probably derived from personifications found in the early cosmogonies), intending to represent that inert power by which nature, as we speak, acts according to its laws.

It must have been observed all along how important a place the nature of Body, *σωματοειδες*, occupies in Plato's philosophy. He has nowhere, however, attempted to give any positive description of the nature of Body. It is, in truth, rather a condition in order to the development of the ideal theory in connection with the phenomena of sensation, than any positive nature, according to his conception of it. He has left it in the most mysterious form: nor does he seem indeed to distinguish it from Space, when he shadows it out by negatives of the attributes of all actual existence. In giving an analysis of production, γενεσις, he enumerates three principles as concerned in the process: 1. The thing produced; 2. That in which it is produced; 3. That from which the thing produced takes the pattern of its production; depicting them under the analogy of the father, the mother, and the offspring.[1] The notion of body is here represented by the intermediate term of the three, namely, that in which the production takes place. "The nurse," "the general receptacle," and "the laboratory," ἐκμαγεῖον, are also expressions by which he endeavours to characterize it, as being in its own nature incapable of being presented to the senses or the intellect. "As a person," he says, "observing a perpetual succession of figures moulded of gold, if asked during the process what was moulded, could only safely answer, that it was gold;"[2] so we must be content to speak of this nature, calling it only a receptacle of forms or species, and not attributing to it any particular species whatever. The tendency of this theory of Body is obviously to remove all material phenomena from the class of real existences. And it seems to point to the origin of Plato's ideal theory in some older philosophy avowedly idealistic. At any rate, the speculation concerning body, as it stands in his system, leaves a hiatus in the transition from the world of Ideas to that of material existence.

The doctrine of Soul, as delivered by Plato, is properly the connecting link between the worlds of being and sensation. Hence is derived the importance of the theory of the immortality of the soul in his philosophy. For it is in the soul that the eternal and immutable is found in the presence of the incipient and evanescent; the intellectual idea in contact, so to say, with the phenomena of sense. The soul partakes of change, as it is connected with the bodily nature: it is eternal and unchangeable, as it is the seat of intelligence.

Soul, then, according to Plato, is the necessary condition for the development of intelligence in the universe, as Body is for the existence of sensation. Soul, therefore, was necessarily prior to Body, as the first condition in order to the constitution of the universe. It was the animating principle by means of which the Deity, when he brought the world out of the disorder and confusion of unreason, communicated intelligence to it, fashioning it after the pattern of the eternal ideas. And not only is the whole universe thus ensouled by the immediate agency of the Deity; but every particular system in it, in which any degree of intelligence is found united with body, has in the very gift of that intelligence a soul originally imparted to it by the Father of the universe himself.

This is the ultimate account of that immortality which Plato attributes to the soul of man. It is not as a *human* soul that it is immortal; but it derives an eternal existence from its being among the original intelligent units of the animated universe. We see indeed a constant production of living things in the world; but it is not, as they have being, that they are thus *produced* or *generated*. This is the result of that "diverse" nature which was blended in their original composition with their higher principles, viz. the natures of "sameness" and "being."

For these are the three principles into which Plato analyses Soul,—the principles of the SAME and the DIVERSE, and BEING;[3] and by these he explains the phenomena of its actual existence. No time can be assigned, then, to the origin of that which by its nature IS, and is the SAME essentially. No one soul, therefore, can now *begin* to exist. And again, whatever once exists can never cease to exist, unless there is anything capable of destroying its principles of Sameness and Being. But Death, as he shews, has no such power. It may disengage the soul from its present body by dissolving the body; but it cannot affect the essential vitality which is in the soul. This essential vitality is the direct contrary to death. It therefore recedes when death comes, according to that law of Contraries, which holds throughout the world of generation and corruption, and which is the agent in all changes. But it still lives as vigorously as ever, and returns to animate another body in the course of Generation.[4] Nor, for the same reason, can it maintain an unvaried perpetuity of existence. It remains ever undestroyed; but from that "diverse" principle which enters into its composition, it both alters in its internal character, and only imperfectly imitates the eternal nature by a successive re-appearance in the forms of new bodies.[5] Thus, whilst it returns to the sensible world, it migrates from the male to the female sex, or to forms of the lower animals, according to that condition of purity in which it departed from its last body, or its previous degree of intellectual cultivation. For, as we may observe, there is no original distinction, according to the theory, between the soul of one man and another, and the soul of man and brute. All are equal in intelligence and goodness, as the immediate work of the Divine Author. The varieties in the characters of souls arise from the operation of the inferior deities who framed the bodies of men and brutes, and the use which individuals may make of their circumstances in the world. Whilst the number of souls, then, remains the same, they are continually changing their habitations, and passing by death from one body to another in the different forms of animal life; undergoing degradation with the forms of inferior animals, or elevation with those of superior nature, according to their state in a former existence.[6]

The theory of the immortality of the soul thus rests entirely on the Theory of Ideas. It is the universality, and being, and truth, and perfection of the Ideas which prove the soul to be eternal.[7] Ideas are found existing in the mind, but their acquisition cannot be traced to any particular period of a man's present life. They have been there from time immemorial, for no one can say when they first appeared in his own mind. They were therefore born with us; and if so, they must have had existence before our birth: and who can limit that existence? They have existed, for ought we know to the contrary, from all eternity: and who, then, shall limit their existence by any future period? why may they not be born with us in a life subsequent to the present, as they were born with us in the present life, and so on to all eternity in endless generations? This is in substance the train of reasoning by which Plato seeks to establish the immortality of the soul. A similar argument has been reproduced in modern metaphysical treatises, variously modified and stated, but the same in substance. How little calculated it is to produce practical conviction, whilst we admire its ingenuity, is evidenced by Cicero's confession, that whilst he wept over the *Phædo*, his mind retained no deep impressions from the argument.[8]

This brings us to the consideration of Plato's ethical system, in its vital connection with his physical and metaphysical doctrines.

The two great principles on which his ethical system reposes, are; 1*st*, that no one is willingly evil;[1] 2*d*, that every one has in his own will a power of inducing changes in his character.[2]

These principles are only the counterpart ethical expressions of his theories of immutable Being, on the one hand, and of the world of phenomena, or mere Becoming, on the other.

For the soul of man, so far as it has any good or truth in it, is framed after the pattern of the eternal Ideas of the good and true. These Ideas, under the various moral aspects which they present, constitute its moral nature. All its desires, therefore, naturally tend to the Good and True. These qualities are what the soul would be. They are the mysterious realities to which it is striving to attain, in all those various efforts after Pleasure which it makes in the present life;—unconscious it may be, as it is in fact in the depraved, of the true nature of the objects to which its affections ultimately point. Still, if it be conceded that Ideas are the only proper Beings, and that everything else is phenomenal, or the mere product and offspring of the generating power of the eternal Ideas, it must also be admitted, that nothing else can be the real source of moral phenomena but the Good and True. In the moral, no less than in the physical world, a constant succession of passing events is found to take place. We perceive a variety of affections in the nature of man as he is in the world, directed to a variety of objects, each aiming at some particular gratification; one desire and its gratification passing away, and others succeeding it in endless flow. All this restless course, then, of moral events exhibited in the life of man is phenomenal; not in the sense of its having no reality whatever, but of its having no permanent reality—of its being no more in the result than effort towards being—restless, endless effort towards that which may give rest and full satisfaction, and stable being.

This ultimate object, then, however indistinctly sought, is the aim of every individual soul of man. Some, indeed, avowedly make mere sensual gratification the end of their desires. They endeavour to satisfy themselves with the limited and the evanescent. But the true cause of all that perverted activity which they display, is the Good itself. They know not what the Good is; but they love it in spite of themselves, and bear evidence, by their life of unceasing pursuit, that they are secretly actuated by the desire of it,—and that they can find no rest in anything short of it. Their soul, originally formed in the likeness of the Deity, can never willingly be separated from its Divine image. In the midst of its wildest aberrations, it feels the attraction of like to like, impelling, and at the same time reclaiming it to right.

This accordingly is Plato's meaning in the principle, which he so emphatically lays down, that "no one is willingly evil." It is very different, we may observe, from saying that no one commits evil willingly. And Plato himself takes care to guard his theory from this misconstruction. He readily grants, that acts of wrong are distinguished by being voluntary and involuntary, without which there could be neither merit nor demerit; but he strenuously maintains that this distinction does not apply to evil itself. It is in all cases involuntary. No one can choose it in itself. It is necessarily the object of aversion, as the good is invariably the object of choice and pursuit.

How is it, then, it will be inquired, that men do become evil;—that whilst they are really seeking to be conformed to a divine pattern, they practically do what is evil, and, losing more and more of their likeness to the Eternal Being, conform themselves rather to the fleeting character of the world of sensation?

The explanation is found in the other great principle of Plato's philosophy, the theory of Becoming, to which we have referred. Change is the characteristic of all that belongs to this subject; as immutability is the characteristic of Being. The course itself of successive phenomena may be varied by impressions from circumstances. In the soul there is a principle of change in the power of regulating the desires,—in indulging them to excess, or moderating them, according to the will. And the circumstances in which the soul is placed, as connected with the sensible world by means of the body, present the occasion for such change. The humours and distempers of the body produce discomposure in the soul. It becomes diseased analogously to the body. This state of disease is what is commonly called folly, *ἀνοια*; and it takes the form either of madness, *μανια*, or of mere ignorance, *ἀμαθια*. Where even ignorance only is the result, the internal harmony of the soul is disturbed. Pleasures and pains are unduly magnified; the democracy of the passions prevails; and the ascendancy of reason is cast down. In addition to these disturbances or ailments through the body, come the influences of evil governments, evil public lessons, evil education. Hence the soul is changed from what it was when it first came from the hands of its Divine author. The eternal Ideas after which it was framed are not effaced from it. This cannot be; for then it would cease to have being; but it loses distinct apprehension of them,—mistakes appearances of good for good itself,—and under that delusion willingly does evil, and presumes on obtaining happiness by a course of evil conduct.

But the same principle of change in the soul gives an opening also for its moral restoration. As the soul is deteriorated by the contagion of the body, so it may also be restored to a sound state by remedial treatment. The yielding to every passing desire, and suffering the desires to grow out of proportion, and destroy the harmony of the soul, is the cause of men's falling into that blindness which hides the good from their mental eye. By restraining them, and moderating the desires, the internal disorder is gradually corrected; reason resumes its ascendancy; the soul once more "sees and hears aright," and thus returns to that good to which its desires naturally tend. It is a long process, indeed, by which the restoration is effected; a process of gradual purification, *καθαρσις*, of the soul, by chastisement and suffering. Nor is it accordingly completed in a single life; many courses of existence must be passed through. Not only is the present life of the soul a consequence of its conduct in a former one; but it is destined to many successive stages of existence, each adapted to the character acquired at the stage next preceding, until its defilements are purged away.

These ethical doctrines of the philosopher, when divested of the extravagance of his theory, so far accord with the truth both of inspiration and experience, as they indicate, that the utmost man can do in the present life is insufficient to restore in him the lost image of God. Whilst they lay down this truth under the disguise of the remedial process of the transmigration of the soul, they further agree with the inspired authority, and with experience, in imposing on man the duty of *commencing* the process of restoration, and in holding him strictly responsible for the state of his mind and affections, through that power of self-direction and capacity of improvement by discipline, with which he has been endued. Thus does he also bear evidence both to the fact of the perfection of man at his creation, and that of his existing corruption. But he differs from the Scripture account of that corruption, in making it originally a physical rather than a moral debasement,

Plato's Writings and Philosophy.

and representing it as taking place by a gradual process, and not by a sudden and entire fall, the effect of a first transgression of a positive divine command.

The Sophists, indeed, boasted of their power of transforming the characters of men, and accordingly made great profession of "teaching virtue."[1] But they coupled with this pretension, the admission, that all opinions on moral, no less than on other subjects, are equally true. All opinions in morals, they said, are true; "but all are not good. What we would effect, therefore, is to lead men to such opinions as we know also to be both good and wise."[2] But this was a mere evasion; for if all opinions are equally true, then must also each man's view of good be true, as well as that which his instructor would inculcate on him; and there is no fixed standard to which he may be conformed. Plato's theory of good, as the sole object of desire,—or the invariable tendency of the will to good, and its invariable aversion from evil,—was a strong ground of opposition to the sophistical doctrine. It pointed out that there was a principle in man superior to instruction, and independent of the accidents of worldly circumstances, the Θεος μετρον, the "God-measure," the fixed Divine standard, to which all moral teaching should be directed, and from a reference to which all moral discipline obtained its value.

From this mode of enunciating the fundamental principles of morals, it followed, that the practical morality which Plato teaches, should be directed to the means of removing the false appearances of good by which the mind is deluded to evil. He shews, accordingly, that there are false pleasures as well as false opinions—that men's ignorance extends, not only to mistakes in regard to their wealth or bodily accomplishments, but as to their moral characters; for that most men think themselves better than they really are.[3] Thus does he apply to morals more particularly, the general confession which his philosophy exacts of its disciple on all subjects, that he knows not what he presumed he knew, and sends every one to learn himself, in order that he may be a moral man.[4]

This, therefore, according to Plato, is the great purpose for which philosophy must be cultivated. Philosophy alone can open the eyes to see the true value of things, and alone elevate the mind from the evanescent region of the phenomenal world to the seat of true and eternal Being.

For the same reason Dialectic, as *immediately* conversant about the Ideas of the good and true, is the ultimate study of him that would seek to educate and improve the powers of his soul to the utmost.

Philosophy and morality, in fact, in his system, perfectly coincide. The love of truth is also the love of good, and the love of good is the love of truth.[5] The same process by which the good man is effected, philosophically viewed, is a power of analysing pleasure and pains, an art of mensuration, enabling the mind to discriminate between Truth and Good on the one hand, and their semblances on the other, and distinctly to apprehend them, under whatever disguise they may be presented and obscured by the senses.[6] Morally viewed, it is the one motive of the love of truth and good predominating over, and purifying, and absorbing into itself, every desire of human nature.[7] In the first view, it is wisdom or philosophy; in the latter, it is purification,—and perfect virtue,—and discipline of immortality,—the resemblance and participation of the Deity.[8]

These views of moral truth are in themselves certainly grand and ennobling. As guides, however, to duty, they are deficient in that particularity and homeliness of application, which are required for the real business of morality. Their tendency, too, to contemplative mysticism is obvious, left as they are by Plato in undefined outline, and clothed in the charms of his imaginative eloquence. Nor shall we wonder that they have easily combined with the feeling of asceticism, so congenial to the human heart. The contempt which they throw over everything belonging to the bodily nature of man,—the delusiveness imputed to the senses, without any limitation of it, or guard against abuse of the theory,—and the abstractedness from the world which they propose,—admit of being construed into a theory of mortification of the body, and of the purifying efficacy of self-inflicted punishments. These tendencies, indeed, of Plato's ethical doctrines, were, not long after his time, exemplified in the apathy and austerity of the Stoic morality. And it is well known to what extent they have been developed in the teaching and practice of religionists of all creeds. It cannot be denied, also, that where they take hold of a morbid and susceptible temperament of mind, they tend to substitute, in such a case, the morality of imagination and sentiment for that of common sense and household feeling, and to fritter away the convictions of duty into mere proprieties of taste; so that even whilst they elevate the character above sordid and vulgar seductions of pleasure, they emasculate and corrupt it, through the very excess of its refinement.

As bad education was regarded by Plato as the other great cause of human corruption, in addition to the influence of Body on the soul, he directs a large portion of his philosophical disquisitions to correct the evil arising from the second source. His ethical discussions go to the limiting of the desires, and curing the diseases produced by them in the soul. His political discussions have for their immediate object, the laying down right principles of education, and enforcing them by the constitution, laws, and power of the state.[9] His two great works, the most elaborate of his writings, the Dialogues of the *Republic* and the *Laws*, are rather theories of Education than of Government and Laws. The former indeed inquires more particularly into the principles on which a right government may be formed; whilst the latter gives a systematic view of the principles of legislation. Both, however, have in view the improvement of human nature by social institutions expressly framed for that purpose. It has been supposed that in the *Republic* we have his theory of a perfect state, and in the *Laws* a practical exemplification of the theory. But this is clearly a mistake. Both are doubtless intended by Plato as theoretical disquisitions on the political matters of which they treat, whilst the real matter in hand is Education.[10] This is expressly asserted by Plato himself, when he compares his legislation to the method of the philosophical physician.

---

[1] Gorgias, however, laughed at the other Sophists for pretending to teach virtue. He professed only the art of words. [2] *Protag.*

[3] Πολυ δε πλεῖστοι γε, οἶμαι, περι το τριτον εἰδος ἐν ταῖς ψυχαῖς τουτων διημαρτηκασιν ἀρετῆς, δοξαζοντες βελτιους ἑαυτους, οὐκ ὀντες. (*Philebus*, p. 285.)

[4] Το γνῶθι σαυτον, λεγεις, ὦ Σωκρατες, κ. τ. λ. (*Ibid.* p. 284.) This is drawn out in a beautiful passage of the *Charmides.* Σχεδον γαρ τι ἐγωγε αὐτο πουτο φημι εἶναι σωφροσυνην, το γιγνωσκειν ἑαυτον, κ. τ. λ. (*Charm.* pp. 130–135.)

[5] Μητ᾽ εἰς τινας ὠφελείας ἐπιστημῶν βλεψαντες, μητε τινας εὐδοκιμιας, ἀλλ᾽ εἰτις πεφυκε τῆς ψυχῆς ἡμῶν δυναμις ἐρᾷν τε τοῦ ἀληθοῦς, και παντα ἑνεκα τουτου πραττειν. (*Philebus*, p. 305.)

[6] *Polit.*; *Protagoras.* He also characterizes it as a knowledge of geometrical equality, opposed to πλεονεξια.

[7] *Conviv.* p. 247, *et seq.*

[8] Διο και πειρᾶσθαι χρη ἐνθενδε ἐκεισε φευγειν ὁτι ταχιστα· φυγη δε, ὁμοιωσις θεῷ κατα το δυνατον· ὁμοιωσις δε, δικαιον και ὁσιον μετα φρονησεως γενεσθαι, κ. τ. λ. (*Theætet.* p. 121.)

[9] *De Legibus*, vii. p. 354.

[10] Πρῶτον δη οὖν προς τον λογον, ὁρισωμεθα παιδειαν τι ποτ᾽ ἐστι, και τινα δυναμιν ἐχει· δια γαρ ταυτης φαμεν ἰτεον εἶναι τον προκεχειρισμενον ἐν τῷ νῦν, λογον ὑφ᾽ ἡμῶν, μεχρι περ ἀν πρὸς τον θεον ἀφικηται. (*Ibid.* i. p. 41.)

When the mere empiric, he observes, should hear such a physician discoursing to his patient of the origin of the disease, and ascending to the speculation on nature, he would be disposed to object that such proceeding was folly; "for it was not healing the sick man, but rather educating him, as if he wanted to become a physician, and not to be made well."[1] The like objection, he says, might be applied to his method of legislation; for, "whoever pursues the inquiry concerning laws," he adds, "as we are doing now, educates the citizens, but does not legislate."[2] And he goes on to say, in the person of the chief speaker, addressing the other interlocutors of the Dialogue, that in their work of legislation they were at leisure, as speculators on the subject, to consider, not what was most necessary, but what was best.[3]

We are not to suppose, then, that Plato had in view the actual foundation of a state, according to the principles of government and legislation laid down in his two famous dialogues. His object was to give an example of the most perfect life,[4] free from those impediments which all existing governments and laws threw across the path of the virtuous man. As philosophy is the guide of private life, elevating it to the knowledge of the Good and True, so he would have philosophy also seated on the throne of government, and exhibit the eternal Ideas of Good and Truth, modifying society after their pattern. Hence it is that he overlooks impossibilities in his arrangements; as is pointed out by Aristotle in his acute comments on the leading points of Plato's political theories.[5] All is sacrificed, in fact, to the one great object of Plato's mind, the sketching of the Idea of the Good as a social principle, apart from the evil influences of society.

The most extravagant hypotheses, accordingly, are put forward in this part of his philosophy; not indeed with a view of their being ever exemplified in any institutions of real life, but in extreme contrast with the existing selfishness of human society, and as theoretic developments of the unchangeable idea of good. Such, for example, is his theory of a community of wives and children, and the training of women to the hardiest exercises of the gymnasium and of war. We justly take exception at the immorality and unnaturalness of such hypotheses. But Plato looks down upon man from the height of his sublime theory. He sees everything in the unity and invariableness of that theory, and overlooks distinctions deeply founded in the nature of man. Thus it is that in his view man himself becomes a thing of little consideration or importance,—a sort of plaything of the Deity, θεου τι παιγνιον, scarcely worth any serious attention. "You disparage altogether the race of man," says an interlocutor in the Dialogue of the Laws. "Wonder not at it," replies the Athenian; "but make allowance for me; for it was from looking off to the Deity, and under this impression, that I said what I have now expressed. However, let it be granted that our race is not insignificant, if you like, but worth some serious consideration."[6] It is in this spirit that he himself sports with human nature, as if human beings were only so many chessmen, to be moved on the board, so as to display the admirable design of the disposing mind, and illustrate the working of the eternal Ideas. His fault is the same as in his physical speculations, that of commencing from the final cause, or the notion of the Best, and forming the world of social life after that, instead of rising from the study of its actual formation to the notion of the Best;—or at least in supposing, that he could arrive at a just view of the divine pattern of Good, by presenting a theoretic copy of it, after his own conceptions of the Best. But such extravagancies as those we have referred to, could only have proceeded from so bold a mind as that of Plato,—a mind, not checked by the repulsiveness of particular consequences from pushing a theory to the utmost.

At the same time, this fundamental notion of the Divine standard and pattern on which he proceeds, imparts a solemn dignity, in the midst of these excesses of the spirit of theory, to the substance of his speculations on government and laws.

Religion is thus secured as the basis of all right government and legislation. That government only which most resembles a theocracy is, in Plato's view, a true polity. All others, popularly termed governments, as democracy, oligarchy, aristocracy, monarchy, are merely settlements of cities, and not *Polities*,[7] being called after that power which has the ascendancy, in each over the other parts of the state. So far as a state is truly such, it ought to be named, he says, after the true God, the lord over all intelligent beings. Governments, as they exist, are only the results of the struggles of contending factions: whence we find, as he observes, one party in the ascendancy excluding and depressing another, in order to its own maintenance, and no concern taken for the welfare of the whole community. To remedy this general evil of existing governments, he would have the simple and straightforward course of the divine procedure brought before the minds of men, and a conformity with that procedure inculcated on them as the only rule of life and happiness. "God," he teaches, in an animated and noble passage,[8] "as the ancient story is, holding the beginning, and end, and middle of all things that are, describes a straight line, according to nature, as he walks his circuit.[9] In his train ever follows Justice, the avenger of those that are left behind by the divine law; to which, he that would be happy, keeping close, follows in the train, humble and orderly; but whoever is puffed up with high boasting, or elated with wealth, or honours, or grace of person, together with youthfulness and folly,—his soul burning with insolence, as presuming, that he requires neither ruler nor any guide, but is competent even to be a guide to others,—is left, forsaken of God. And being left, and taking to himself others besides, such as he is, he frolics, throwing everything into promiscuous confusion. And to many he seems to be some one; but, after no long time, undergoing a retribution, of which he cannot complain, to Justice, he utterly subverts himself, and his house, and his city."[10]

Here we have emphatically recognized the great truth, that the foundations of all government and law are laid in the unchanging nature of the Divine Being. The law of right, as exemplified in the dominion of party, is the law of the strongest, fluctuating with the accidents of power, and never attaining to any permanent being. Such was the law of right, as taught by the Sophists, from city to city, and which was fully established in public opinion throughout Greece,—not only as manifested in the factious character of the particular governments, but avowedly declared and acted on as a principle of conduct. "It is nothing," say Athenian ambassadors, "out of the course of the established opinion of men concerning the Divine Being, or

Plato's Writings and Philosophy.

their sentiments concerning themselves, that we expect or do. For we hold that the Divine Nature, so far as we can judge of it, and human nature, as we see clearly, by an instinctive necessity, ever exercise power where they can obtain the mastery. Nor are we the first, either to propose the law, or to use it when laid down: it was in being when we took it up; and it will subsist for ever, for us to transmit to others after us; and we merely act upon it; convinced, that yourselves, no less than others, were you placed in the same power in which we are, would do so."[1] Here, then, is the law which belongs to the region of instability,—to that nature which is ever *becoming*, and never *is*. Contrast with this Plato's principle, which deduces the origin of law from the eternal IDEA of GOOD, and it will then be more distinctly seen what the spirit of Plato's legislation really is.

It follows, indeed, from his principle, that all instituted law is imperfect.[2] And he admits, accordingly, that if a perfectly virtuous ruler could be established on earth, it would be best that the business of government should be carried on by his will; which would in such a case be only the copy of the Divine exemplar of right. But as this is past hope in the present condition of human things, the substitute for the more perfect system is the institution of laws framed after the eternal Idea of Good; not laws adapted merely to the preservation of a particular form of polity, but embodying in them the immutable principles of right. And even such laws, as being matters of institution, are inferior in dignity to unwritten laws—the principles of right—which, themselves resting on no external sanction, are yet the conserving principles of all positive laws.

Having his eye fixed on the eternal pattern of the good and the true, Plato looked with a feeling of disappointment and disgust at the several forms of polity which the states of Greece exhibited. He is generally thought to have inclined to a preference of aristocracy, and to have regarded with aversion all popular government. But though it is probable, that, from what he saw of the tyranny of an unrestrained democracy, he sighed in secret for a better order of things, we cannot conclude from his political speculations that he regarded any single polity as the best. He, in fact, condemns all particular forms;[3] and when he asserts a preference, it is for a polity such as was nowhere seen in his times, combining in it monarchy, aristocracy, and democracy.[4] But in his view, as governments then existed, they were all one-sided; the dominion of one part of a community over the rest, and not the dominion of good over the whole. This dominion, as we have observed, was only to be found in the government of God over the world, and to it, therefore, he would have all human government conformed. His sole preference, then, is for a theocracy, if such could be realized on earth. His slighting manner of speaking of the lower orders of society, and of all indeed but those who are gifted with superior talents and other natural endowments, is to be ascribed to his general low estimate of human nature, considered apart from that cultivation, which the highest and most intellectual studies impart to it.

Respect for antiquity and prescriptive authority is strongly inculcated by Plato. In nothing was the changeableness of all generated things more evident than in the ever-varying forms of the states of Greece, and especially of Athens itself. The democracy of Athens had been an universal market, παντοπωλιον, as Plato terms an extreme democracy of all sorts of polities.[5] And laws had so far lost their force there in the most corrupt times, that everything was transacted by the decrees of the day; the variable determinations of popular assemblies being substituted practically in the place of the records of former experience and wisdom. Early legislators had devised expedients for counteracting this love of change on the part of their countrymen, as Solon, for instance, and Lycurgus, had done. And in some instances, we find a temporary and partial expedient adopted, by the popular assembly itself fixing the penalty of death to the proposal of rescinding a measure before a certain period.[6] Plato's expedient was supplied by the principle itself of his philosophy. If the Idea of Good was eternal and unchangeable, the constant pursuit of change must lead men astray from their happiness and the truth. They must be called back, therefore, from that which is present and passing, to the recollection of the past. They must not look on wisdom as a thing which is different to-day from what it was yesterday, or in former times, but hold it as what by its very nature is unalterable. To regard it as susceptible of improvement in the lapse of time, would be to deny its proper Being, to reduce it to the condition of mere Becoming. A distrust in the wisdom of any existing generation of men, and a sacred reverence for that of former generations, and especially for the earliest traditions of knowledge, would naturally be inculcated in such a philosophy. Thus he highly commends the Lacedemonian and Cretan polities for the provision, that no young man should inquire whether the laws were good or bad, but that "all should with one voice and with one mouth agree in declaring that everything in them is well appointed, as being by the appointment of gods;" and that no other sentiment should be allowed to be expressed. Further, not even does he permit a young person to be present when such matters are considered by the old.[7] In the same spirit, the Egyptian immutability in the arts for thousands of years, is admired, as a proof of admirable legislative and political wisdom.[8] Even in regard to the fine arts, and to sports and amusements, he reprobates the tendency to innovation, as dangerous to the serious institutions of a state, on the ground, that changes in these lighter matters "imperceptibly change the manners of the young, and bring what is primitive into disrepute, and what is modern into repute;" and that there cannot be a greater mischief to states than such a habit of "blaming antiquity."[9]

All this, which under certain limitations may be true, appears, when thus broadly laid down by Plato, a misapplication of the proper sanction of religious truth to truth in general. In religion, the only question being what is really taught by its Divine author, there can be no addition made in the course of time to the truths revealed, except by another divine revelation, though there may be advancement in the exposition and teaching of it. What is primitive and ancient, accordingly, in this subject, once fully ascertained to be so, is the truth, and the whole truth. Only we must not mistake antiquity of exposition and comment, for primitiveness of the truth itself; for these admit of improved knowledge by human study, when the original truth itself does not. The contest between the advocates of the respective claims of the past and of the present, in the matter of knowledge, is doubtless much older than the time of Plato. But his authority and eloquence have probably been mainly instrumental in starting and sustaining the controversy in modern times, through the early reception of his philosophy into the literature of the Christian church.

But we may further see a reason for the stress which Plato lays on the wisdom of prescription and authority, in that state of public opinion to which he is addressing himself. It was not, as might be supposed, a state of things corresponding exactly to a demand for religious or civil changes, in our days, under established governments and institutions. The question of change is now gravely discussed, and deliberately carried or rejected, not with the view of unsettling everything, but in order that some particular institution or law may be *established* for the future. Except in violent outbreaks of human passions long pent up within artificial restraints, exasperated by resistance, and at length forcing their way out, and levelling all barriers before them, as in the instance of the French revolution, it cannot be said with truth, of the struggles for particular changes in modern institutions, that they have been actuated by the mere desire of change, and the hatred of everything established. The religion and the civilization of modern times have in some measure presented a check to this. But at the centre of movement in Greece, change was the order of the day. Athens would neither rest itself, nor suffer other states to rest. When its very demagogues are forced on some occasions to endeavour to repress this incessant changeableness; as Cleon was, when he told the Athenians it was better "to have worse laws unmoved, than good laws perpetually changed;"[1]—it is evident that the spirit of change was then developed in its most fearful form. For we find the magician himself who had evoked it, starting in terror at the apparition, and finding it too strong for his direction and control. *Δοῦλοι ὀντες τῶν ἀει ἀτοπων, ὑπεροπται δε τῶν ἐιωθοτων*, "Slaves of every new extravagance, but despisers of accustomed things,"[2] are the words with which he attempts to exorcise it, and which the historian of the times puts into the mouth of one who, as the creature of the system, could most pointedly characterize it. Such was that spirit, then, against which Plato had to contend. It was an enemy not only to the existing government, but to all government, and all law, and all religion and morality. It demanded, therefore, the most forcible counteraction. It was to be met by inculcation of the opposite. According to his own universal principle, contrary was to be expelled by contrary. Everything that was ancient was to be upheld, accordingly, as worthy of veneration and acceptance, simply because it was ancient. The voice itself of antiquity, though speaking without evidence, was to be received with implicit acquiescence and submission. Thus it is that Plato is found strenuously appealing to the instinctive feeling of his countrymen, which they still retained in spite of the prevailing folly,—the feeling with which they so fondly reverted to their early glories, and delighted to view themselves in the past;—and labouring to correct their vacillations of present opinion by recalling them to the stable lessons of *memory*.

Political philosophy, then, according to Plato, is the history of those changes which the will of man produces in the matter of government and laws, and an endeavour to limit those changes by restoring in the social world the primitive order and rule.

Education is the means by which those changes are counteracted. It avails itself of that principle of contrariety by which all changes are carried on; and endeavours to expel the evil by inducing the good. The process by which it carries on this effect is, a discipline of the intellect, prescribed by the state, and promoted by all its institutions and customs, framed, as these are supposed to be, after the idea of the Sovereign Good. That discipline lays down a course of exercise for the body as well as for the intellect, that the body may be brought into the best condition, in order to the exercise of the intellect. The intellect itself it conducts through the steps of the several sciences, from the bodily and sensible to the unembodied and intellectual,—from the phenomenal and changeable to that which has real being, and is unchangeable. And thus in Plato's system it is classed under the two comprehensive heads of Gymnastics and Music; the latter term being understood, according to its derivation, to denote literature in general. Philosophy itself was the ultimate attainment of education,—the result of the whole intellectual training of the accomplished man. Ostensibly, under this system, there was no peculiar discipline of the heart. Indirectly there was; so far as it inculcated purification and self-denial. But the strengthening and elevating of the intellect was its direct object. Its tendency was thus to exalt the virtues of the intellect above those of the heart; and, in opposition to the evidence of facts, to assert the power of knowledge over the determinations of the will. Not that Plato denies the existence of what we call self-command, or that controlling of the passions which is the result of a previous struggle with them. But he did not admit (as Aristotle does, and urges against him[3]) that reason could ever be overpowered by the passions, or that if there were a distinct knowledge of the truth in the mind, it could give way to passion.

In the matter of Religion, Plato's theory of Ideas led him to see that there were truths above the evidence belonging to Experience, and which must be received solely on the ground of the Divine authority. For whilst he taught that the mind of man must work its way up to the Ideas by a course of argument and examination of evidence, yet, having reached the Ideas themselves, it had attained the ultimatum of truth; no further evidence of these was to be sought; they carried their own light in themselves. So, when any truth was presented to the mind, which related immediately to the Divine Being, it was not to be supposed capable of being examined in itself, and established on any higher ground of internal evidence, but must at once be admitted, if there were sufficient external authority for it. The only question respecting such truths is, are they *historically* true? Is it certain, or at least highly probable, that they have descended to us from the Father of Lights himself? Have we reason to think that they were originally real divine communications,—and are they vouched to us as such by a competent evidence?[4] Now, in regard to the primary principles of the mind, such as we have before spoken of, though they are not evidenced by any higher principles, or by any conclusions from Experience, they carry their own evidence, by their invariable presence in the mind on certain occasions, being naturally suggested by such occasions to every rational understanding. But the truths of religion are of a different nature. They cannot be authenticated by the mind itself to itself, as being out of its range of thought. They must therefore be authenticated from without. And in regard to these, accordingly, we must appeal to the Reason and Word of God, as the simple, and proper, and unanswerable vouchers of them.

This is the account of Plato's disclaimer of all evidence, either of demonstration or probability, on matters strictly divine, and his frequent appeal to mythic traditions when his discussion touches a mystery of the Divine Being or the Divine conduct. He resolves the whole authority of such matters into the evidence of "ancient story," *παλαιος λογος*,[5]—and "primitive hearing," *ἀρχαια ἀκοη*,—and "learning hoary with time," *μαθημα χρονῳ πολιον*.[6] In speaking of the generation of the subordinate divinities, in the *Timæus*, he makes an observation applicable to the whole subject of divine things as treated by him. Instead of entering into explicit accounts of them, he observes that the subject is "too great for us, and that we must believe those who have spoken before, being the offspring of gods, in the way in which they said it, and because they must be conceived to have known their own ancestors;" adding, that we cannot refuse credit to the "sons of gods, although they speak without probabilities and necessary demonstrations, but must follow the rule of believing them on their word, as declaring what belongs to them."[1] He commends, too, the primitive generation of men for their docility in following rules of life founded on oral tradition,—their "holding as true what was said τα λεγομενα, concerning both gods and men."[2] Again, speaking of the state of the dead, and their interest in the concerns of men on earth, he appeals to the same kind of evidence. "We must believe," he says, "the voices of others in such matters, so current as they are, and so extremely ancient; and it is enough for our belief that legislators, unless they be proved absolutely unwise, have asserted them."[3] So justly does he insist on the reasonableness of being content with the voice of a declaratory authority in matters incapable, by their nature, of a direct evidence from our reason.

[6] *Timæus*, p. 291.

By the heathen philosopher, in the absence of an authentic revelation, the authority for such truths was naturally sought in ancient traditions,—traditions mounting up beyond all memory of their origin, and therefore referable to times when the world was yet fresh from the hand of God. The voice of remote and undefined antiquity, indeed, by a natural delusion, represents itself to the mind as but little different from the sanction of eternal truth. For it is but a slight and imperceptible transition from the indefinite to the infinite. Many such traditions were found in the heathen mythology, connecting themselves with another order of things, when gods conversed with men on earth. Some of them, certainly, were full of absurdity and profaneness; and all were disfigured with the colouring of fable; but still there were some, beautiful in the conception, and sublime and impressive in the doctrine. Of this latter character, for the most part, are those exquisite mythical legends, with which Plato has diversified his discussions, throwing the solemnity of religion over truths which he would especially enforce.

Thus, though he has elaborately argued the immortality of the soul, he is not content to leave the question on those abstract grounds of conviction. He feels that the conviction which may practically influence the conduct, must be drawn from another source,—that of a simple belief in some authority declaring it,—when he closes the discussion, as in the *Phædo*, and in other places, with a scenic representation, from the legends of ancient tradition, of the doctrines which he has been enforcing. The whole of the *Timæus*, in fact, is a legend rather than a philosophical inquiry. It appeals, for the reception of its truths, to the shadows with which it veils them, and the mystic echoes of sounds heard by the listening ear from afar. In that legend, indeed, we have very considerable evidence of the pure source, from which the heathen world drew much of the sacred truth that was wrapped up and disfigured in their fables. We perceive in such a document of ancient philosophy, at once the sure and wide-spread knowledge resulting from a scriptural Revelation, and the obscurity and fallibility of the information of Tradition. To this effect are the description in the *Timæus*, of the universe as the "one" work of the "one Supreme Being,"—as the "visible likeness of one himself the object only of intellectual apprehension,"—as the "only-generated," μονογενης, of the Father of all things; and the strong assertion of the goodness, and beauty, and perfection of the universe; and particularly, in reference to this, that striking passage, "When the Father who generated it, perceived, both living and moving, the generated glory of the Everlasting Divinities, he was filled with admiration, and, being delighted, he further contemplated the working it still more to a resemblance of the pattern."[4] Add to these instances the simple and magnificent words which he has put into the mouth of the Father of the Universe, as an address to the generated gods, respecting the formation of the bodies of men and other living creatures.[5] The attributing to Him a speech at the first formation of man, is alone sufficiently remarkable; and the plural address with which it opens, makes the correspondence still closer to the sacred words, "*And God said, Let us make man in our image, after our likeness.*" The order of the generation of things, it may be further observed, agrees with the order of the creation. First the heavens and the earth are produced, and then the living creatures; and among these Man, designated as "the most religious of animals."[6] But at the same time there is much confusion and degradation of the high subject. We look in vain for those sublime features of the inspired account, that the creation arose out of nothing, by the word of God. This is darkly intimated in the shadowy nature which the narrative assigns to Body; but, though it be but a shadow, Body still subsists in his system, as the co-eternal contrary of the Divine Intelligence. Traces of the descent of holy truth, in the like disguise, appear in the references found in Plato to early deluges and genealogies;[7] to the notion of God as the shepherd of his people;[8] and to accounts of variations in the course of the rising and setting of the sun.[9]

Such, then, is the character of Plato's philosophy, both in its general method, and in its results, as a theory of the universe, and an information respecting the leading branches of human knowledge.

It was concerned, we find, more in investigating and establishing first principles, than in drawing out results; in exciting the love of wisdom, rather than in aiding in the research after it. With him, indeed, philosophy and its method of inquiry, as we have seen, are one; and, in like manner, philosophy and its several branches coalesce in his system into one. We have spoken of his logical, and physical, and ethical doctrines, as if they were distinct subjects; but in his mind the one theory of Ideas held these several doctrines in its embrace, and made them indissolubly one with itself. For his design throughout is, to establish universal principles common to every subject, and on these to build a structure of philosophy,—a counterpart in the human mind to the universe itself, and comprehending therefore all that relates to the Deity, to man, and to the world. He would place the mind of the philosopher far above the scenes in which man lives, and endue him with a keenness and range of vision, extending over the whole region of speculation, and leaving no part, either from its largeness or from its minuteness, unexplored. The problem which he undertakes to solve is, how all things are both one and many; how, amidst the multiplicity of phenomena with which we are surrounded, a real unity still subsists and pervades the whole. He proceeds on the conviction, that to attain to this unity, so far at least as our faculties will enable us to attain to it

Plato's Writings and Philosophy.

(for in itself it is incomprehensible and ineffable), is to find the clue to that maze of sensible things which bewilders human observation. He was not intent, therefore, on distinguishing and arranging the several branches of knowledge, but on bringing all into subjection to his commanding theory of the perfect unity. He has not, in fact, elaborated, or even sketched, any one particular science. He has shewn how the sciences may be distributed, or rather furnished hints for such a distribution. But he has left the task of doing so to others after him, as subordinate agents, filling up the details and supplying the omissions of his system. His was characteristically a one-making mind. It analysed,—not, however, for the purpose of finding and arranging the component elements of a subject, but in search of the one vivifying principle, which gives form, and truth, and goodness, and beauty, to everything. He omits, accordingly, to examine with minuteness into secondary agencies, which are the proper study of the particular sciences, in order that he may direct attention to the master-principle, by which all subordinate principles are held together, and by which they work as concurring causes in the infinite variety of actual phenomena with such energy and constancy of operation.[1]

It was left for his pupil Aristotle to take up the business of philosophy where he had designedly left it unfinished, and, by a more rigorous method, to introduce order into the field of science, by assigning to each particular science its distinct objects and office.

It required, indeed, some philosopher worthy of such a master to take up the subject where Plato had left it, and to carry it out to the fulness of an instructive method, and a systematic exposition of truth; and such a successor was found in Aristotle. Aristotle, as controverting the Theory of Ideas, may perhaps be regarded by some as an antagonist, rather than a successor, to Plato. But every succeeding system of philosophy is partly a polemic against its predecessor, by whose labours it nevertheless has profited. So it was with the great movement of mind commenced by Plato. It languished under Speusippus and Xenocrates, and the still more remote successors in the Academia. But in the Lyceum, the rival school in name, but the rival only as the vigorous offspring of the declining parent, a crowd of hearers such as that whom the great magician of the Academia had called around him, was once more assembled, and Athens again assumed the form of an university. In Aristotle's system, accordingly, we see the productiveness of those germs of philosophy which the genius of Plato had planted and reared. Others cultivated the germs themselves; and some fostered them into a wild luxuriance. It was by being engrafted on the sturdy stock of Aristotle's mind, that they received fresh vigour, and produced fruits, though not strictly their own, yet partaking of their life and richness.[2]

If we take Plato's philosophy as a whole in its complex form, not simply as a system of philosophy, but a system in which philosophy, and eloquence, and poetry, and deep religious and moral feeling, are harmoniously combined, it stands alone in the history of literature. There is nothing which approaches to it under this point of view, nothing which may be properly regarded as a continuation of it. It is a splendid work of rare genius, like the Homeric poems or the Minerva of Phidias, which no other artist has ever equalled. Philosophical dialogues have been written in imitation of those of Plato; but how unlike to them, how altogether inferior to them in conception and execution! There is learning, and eloquence, and grace, in whatever the accomplished mind of Cicero has touched. But compare his most finished specimens in this way with the Dialogues of Plato, and what a deficiency appears! Dignity and refinement of mind, and an acquaintance with the stores of philosophy, shine forth in the Dialogues of Cicero. But we miss altogether the depth and the exquisiteness of thought, the range and the minuteness of vision, the exactness of reasoning, the lively sketches of character and manners, which interest and astonish us by their combination in the Dialogues of Plato. Xenophon had great knowledge of human nature, and has thrown an air of great naturalness over his simple descriptions, whether it is conversations and moral lessons that he relates, or stirring scenes of history. But his Socratic dialogues do not admit of comparison with the elaborate efforts of Plato. They were clearly intended only as accounts of what Socrates had taught, and did not aim at any artist-like effect, as compositions. Or, if we turn to the *Symposium* of Plutarch, there, again, much as the author admired and studied Plato, we observe an entire want of that tact in the management of the dialogue, which so engages our attention amidst the subtilties of Plato's discussions. If we compare, again, the imitations of Plato in the Dialogues of Berkeley and Shaftesbury, we find the like contrast as in those of Cicero. Superior as these are in composition to other efforts of the kind in our language, they still give no proper representation of the spirit or the form of the Platonic Dialogue. There is no life in the interlocutors of these Dialogues; and the author himself is scarcely concealed behind their masks. Nor are there any touches of natural feeling or incident to connect the argument with the personality of the speakers; such as those in the *Phædo*, where the discussion opens with the loosing of the chains from the limbs of Socrates, his bending and rubbing his leg, and expressing the pleasure arising from the contrast of his pain before; circumstances, not merely thrown in by way of dramatic interest, but leading, in immediate application, to the argument in hand. As we have said, then, the philosophy of Plato taken in connection with the admirable compositions in which it is contained, stands alone in the history of literature. It is due to the charm of the composition, that the interest of the reader is sustained amidst much of dry abstract speculation, requiring the closest attention, and considerable acquaintance with the subjects of philosophical discussion, in order to follow it. It was this charm in great measure, doubtless, which rendered the writings of Plato, in spite of their abstruseness and subtilty in many parts, so acceptable to Grecian taste. He had his critics also and censors; but all seem to have concurred in placing him at the head of the philosophical writers of Greece. Objection was taken by some to the severity of his sarcasm against the leading Sophists and other great names. Complaint, too, was made of his putting sentiments and words into the mouth of Socrates which Socrates had never used; and of his anachronisms, in bringing together in conversation, persons, who, from the period at which they flourished, could never have met. But these were merely minute criticisms. It was seen by those who entered into the spirit of his writings, that he was still the great master throughout,—that he was not giving, in his Dialogues, a history of individuals or of the times, but a general character of classes of men, and the prevailing tone, both of philosophical discussion and of popular opinion. The enlightened critic saw that Socrates, for example, is not pourtrayed by him simply as Socrates, but as the characteristic spokesman of the system on which he is engaged;—and in like manner, that when he brings together persons of different periods, he overlooks the anachronism, that he may enunciate the doctrines inquired into, in their proper person.

The perfection to which he wrought the style of his most elaborate Dialogues, will be apparent to those who study them accurately under this point of view. So fastidious, indeed, is the taste with which they have been wrought into their present form, that it cannot be duly appreciated without an accurate and even delicate observation. Every word seems chosen with care, and every clause of his periods made to flow with its proper rhythm; and this effect at the same time is produced out of the ordinary materials of the language. The words and idioms are those of conversation, and the way in which they are put together seems, at the first view, to be as unstudied as mere conversation. But the result is an exquisite composition, in regard to which we are at a loss to pronounce, whether the depth and the elegance of the thought, or the grace and propriety of expression, most prevail.[1] It is quite evident that he was not the first to compose Dialogues, were we to look simply to the finished form in which his Dialogues have been executed. They are, doubtless, not the first efforts in that way. But the school of Elea had preceded him in this style. More particularly, however, we are told, that Alcamenus of Teos was the first to write Dialogues; or at least his is the earliest name to which, on the testimony of Aristotle, in a work now lost, the honour of originating the Dialogue has been assigned. But we need look no further than to the Greek drama for the first thought of the Platonic Dialogue. The Mimes of Sophron, and the Comedies of Epicharmus, probably furnished materials from which he was enabled, if not to mould, at least to enrich his Dialogues. The Mimes of Sophron, indeed, it is said, found a place under his pillow.[2] And what are the *Protagoras*, the *Gorgias*, and the *Symposium*, it may be asked, the particular Dialogues in which he has most fully displayed his dramatic power, but philosophical comedies in prose, analogous to the *Clouds* of Aristophanes, and only differing from that play, as addressed to a higher class of hearers, and as intended, not to call forth the applause of spectators, but to elicit thought from a reader.

---

[1] Ταῦτ' οὖν παντ' ἐς, των ξυναιτιων, οἷς θεος ὑπηρετουσι χρηται, την του ἀριστου κατα το δυνατον ἰδεαν ἀποτελῶν. (*Tim.* p. 336.) The genesis of the universe is from the union of νους and ἀναγκη, and the dominion of νους over ἀναγκη causes ἀναγκη to bring τῶν γιγνομενων τα πλειστα ἐπι το βελτιστον. (*Tim.* p. 339.)

[2] Dionysius of Halicarnassus speaks justly of Aristotle, as ὁ γνησιωτατος αὐτου μαθητης. (*Ep. ad Cn. Pomp.*)

Nor, in touching upon the peculiar excellencies of Plato's Dialogues, ought we to omit to notice especially, under this point of view, the delightful mythic narratives, with which he has adorned and relieved his abstract discussions. The art with which he has introduced them is most admirable. They are openings of rich scenery, suddenly presented to the view when least expected;—tales of an Arabian night succeeding to a morning's pastime of disputation in some school of Greece;—solemn shadows from an unseen world, casting their majestic forms over some ordinary incident of daily life. But they are not to be regarded only as embellishments and reliefs to the argument. They bear an important part in the teaching itself of his philosophy. They soften down the outline of his reasonings,—taking from them that positive didactic form in which they might appear, amidst the strife of debate, and as wrought out by discussion. The knowledge which his theory aims at imparting, is that of Reminiscence, as we have shewn; and he would not, accordingly, have the results of his inquiry present themselves as anything else but Reminiscence. We are, indeed, to search out the reasons of things. We are not to rest in mere opinion, but to battle our way against error and falsehood, until we rise to the eternal Ideas, the causes of all knowledge, as they are the causes of all Being. Still, we are not to suppose that we can distinctly comprehend the eternal Ideas in themselves. Though they are at last intellectually discerned, it is only "at the last," and that "scarcely."[3] For they carry up the eye of the soul to the fountain of all knowledge,—the Divine Being himself, who cannot be conceived, much less defined in words.[4] The mythic legends admirably combine with the refutative form of the discussions to leave this impression of indefiniteness on the mind. Whilst the mind's eye is directed steadily to the objects which can alone give stability and certainty to its knowledge, we are thus throughout reminded by Plato, that we live amidst shadows and darkness, and that our eye must be purified and endued with heavenly light before it can look undazzled on the TRUTH itself. (I. I.)

PLATONIC, something which relates to Plato, his philosophy, his opinions, or the like. Thus, Platonic love denotes a pure and spiritual affection, for which Plato was a great advocate, sa subsisting between the different sexes, abstracted from all carnal appetites, and regarding no other object but the mind and its beauties; or it is even a sincere, disinterested friendship subsisting between persons of the same sex, abstracted from any selfish views, and regarding no other object than the person, if any such love or friendship has aught of a foundation in nature.

PLATONIC Year, or the *Great Year*, is a period of time determined by the revolution of the equinoxes, or the space wherein the stars and constellations return to their former places in respect of the equinoxes. The Platonic year, according to Tycho Brahe, is 25,816; according to Ricciolus, 25,910; and according to Cassini, 24,800 years. This period once accomplished, it was an opinion amongst the ancients that the world would begin anew, and the sameseries of things return in the same order as before.

PLAUEN, a city of the kingdom of Saxony, in the circle of Voightland, and the capital of a bailiwick of the same name. It is situated in a beautiful valley upon the banks of the Elster, is surrounded with walls, and contains 608 houses, with 7200 inhabitants, more than one half of whom are employed in making muslins and other kinds of cotton goods of fine quality. Woollen cloths, paper, and hosiery, are also extensively fabricated.

PLAUTUS, M. ATTIUS, the father of Roman comedy, was born of humble parents, in the Umbrian village of Sarsina. He flourished during the second Punic war; and his death happened B. C. 184, when Terence had reached his ninth year. Of his private circumstances we are entirely ignorant; but fortune, which had blessed him with extraordinary talents, does not appear to have been very bountiful in worldly goods. To gain a livelihood, he was compelled to have recourse to the most laborious employments; yet still he contrived to write comedies, by the sale of which he added something to his enjoyments. The number of comedies composed by Plautus, or at least known under his name, was, according to Aulus Gellius, about one hundred and thirty, of which L. Ælius considered only twenty-five as genuine productions. Gellius imagines that the others, if they were not composed by Plautus, belong at least to the poets of that period, and had been read and amended by him; so that in this manner they had acquired his style and character. Varro considered as genuine only twenty-one, which were hence called *Varronianæ;* and perhaps a few others, from their similarity of style. Changes in the text and in the arrangement, which were brought about at the will of the ædiles, to whom he sold the plays, and even of the actors who were employed in performing them, became still more frequent after the death of the poet. The substitution, too, of the plays of another unknown poet, Plautius, for those of Plautus, has increased the difficulty of distinguishing the genuine productions of the poet from those erroneously ascribed to him. Thus we find grammarians and critics, such as Ælius, Volcatius, Sedigitius, Claudius, and Aurelius, writing treatises respecting the genuine pieces of Plautus. The number of comedies which have been preserved, though by no means quite perfect, amounts, according to Varro, to twenty. The *Querolus* or *Aulularia,* written in prose, though found in the manuscripts of Plautus, and even cited by Servius as belonging to him, is considered by some as of a later date, probably of the time of the younger Theodosius. Vossius and Tirlemont considered Claudius Rutilius Numatianus as the author, whilst Vincent was rather inclined to suppose it the production of Phædrus, the celebrated writer of fables. All the manuscripts of Plautus which have yet been discovered, with the exception of the Palimpsest of the Ambrosian Library, seem to be of a recent date, and must have flowed from a common source, as the same passages are corrupt in all.

---

[1] The fastidiousness of taste with which he touched his compositions, is illustrated by the account of the opening of the *Republic* having been found with the clauses variously transposed. Dionys. Hal. *De Comp. Pub.* 25.

[2] Diog. Laert. in *Vit.*

[3] Ἐν τῷ γνωστῷ τελευταια ἡ του αγαθου ἰδεα και μογις ὁρασθαι. (*Rep.* vii. p. 133.)

[4] *Tim.* p. 303.

It is usually supposed that we are indebted to the grammarian Priscian for the order in which we find these twenty plays arranged; and he, too, is the author of the short arguments prefixed to each comedy in some of the old manuscripts. The purity of the language proves their remote antiquity, even though we be inclined to think that Plautus is not the author. The plays are found generally in the following arrangement. *Amphitrus,* called by Plautus himself in the prologue a tragi-comedy, because gods and princes are the principal characters, and tragic events are brought upon the comic stage; it has been imitated by Boccacio, Molière, and Dryden. *Asinaria,* in imitation of the Greek play 'Οναγρος of Demophilus, exhibiting in strongly-marked characters the corruption of Greek manners. *Aulularia,* one of the best, distinguished by its Roman colouring; but its end is wanting: it is the foundation of Molière's *Avare.* *Captivi,* according to the opinion of the poet himself, one of his most successful efforts, which is recommended particularly by the moral feeling that pervades it. The subject is more grave, and the coarse licentiousness and extravagance which disgust us in his other plays are here thrown into the back-ground, whilst a purely moral character steps forward, without any diminution in the comic vigour and genius of the poet, who must have written it in the latter years of his life. *Curculio,* from the name of the parasite who acts the chief part. *Casina,* in imitation of the Κληρουμενοι of Diphilus. *Cistellaria.* *Epidicus,* a play highly thought of by the author. *Chrysalus* or *Bacchides,* in which the prologue and beginning are wanting: the copy which Lascaris pretended to have found in Sicily is not considered as genuine, being probably the work of Petrarch. *Phasma,* or *Mostellaria,* in modern times imitated by Reynard and Addison. *Menæchmus,* also imitated by Reynard, and even by Shakspeare in some parts. *Miles Gloriosus,* one of his most successful pieces, which reminds us of Holbein's Bramarbas. *Mercator,* in imitation of the 'Εμπορος of Philemon. *Pseudolus,* one of the favourites of the poet, as appears from Cicero. *Pœnulus,* represented probably about 191, and therefore to be numbered amongst the latest plays of Plautus. This is proved by the labour he has bestowed upon it, the superior manner in which it delineates character, and the skilful arrangement of the whole. It is remarkable for the introduction of Carthaginian words, the only monument of the language which remains, with the exception of coins and inscriptions; and it has therefore been frequently referred to by the learned of ancient and modern times. *Persa,* from which Pliny quotes some verses that are not found in the play which has come down to us. *Rudens,* a beautiful play, in imitation of the Greek of Diphilus. *Stichus.* *Trinummus,* in imitation of the Θησαῦρος of Philemon: after the *Captivi,* it is the most remarkable play, both in regard to the design of the whole, and the delineation of character, as well as in the skilful arrangement of individual parts. *Truculentus,* also a favourite of the poet. Besides these, we have likewise the names and fragments of many other comedies.

These comedies belong to the class of *Comœdiæ Palliatæ,* and are so far to be considered as free imitations of the works of the Greek comedians of the new school; yet it would be doing injustice to the talents of Plautus to suppose that he imitated slavishly the Greek originals, and copied their works without asserting his own intellectual powers, or making changes both in relation to the form and design of the whole, as well as of its individual parts. The bold manner in which he made use of the Greek materials, by which the poet was able to bring into play his natural genius and vein of comic humour, and the frequent introduction of Roman characters and customs, even into the midst of Greek plays, distinguished Plautus from the polished Terence, who adhered much more closely to the Greek originals. It marks him as the genuine poet of the people, who knew how to create a popular drama, and thereby to furnish amusement for the lower ranks of life. He sold his plays to the ædiles, and therefore must have written them expressly for the diversion of the people. We need scarcely doubt that the poet would have taken a still wider range, and have exhibited still more of the true national character of the Romans, if he had not had before his eyes the fate of Nævius, to warn him from the dangerous path on which he was entering. The entire loss of the Greek originals prevents us from being able to decide how much of his materials the poet borrowed, and how far he imitated them in the design and conduct of his plays. Plautus must have made more use of the productions of the Attic comic writers than of those of the Sicilian poets. Yet Epicharmus and some others he had evidently read with much care, and may also have imitated them, as he certainly did in respect to Theocritus. The prologue, which is generally thought to have been wanting to the Greek comedy, was peculiar to him and his imitators. The poet was chiefly distinguished by the raciness of his wit, and the original and spirited manner in which he treated his subjects. But as it was not the higher and more polished classes of society for whom he wrote, but rather for those in humble life, from which he himself had sprung, we may expect to find in his comedies much low buffoonery, as well as many words and expressions bearing a double meaning; and here and there he oversteps the bounds of modesty and decency, which may however be forgiven, in return for the rich vein of humour which will always stamp Plautus as one of the most original of the comic poets of Rome. For this reason, however, much caution ought to be used in introducing the young to an acquaintance with the writings of Plautus.

The language of Plautus is natural and forcible, though not always harmonious and musical. Neither is it free from a certain harshness and ruggedness, apparent in the use of old forms of words and expressions, which became obsolete in later times, though we may ascribe this to the still uncultivated state of the language. The form of the verse is not regular; indeed the prosody and metre are both treated with so much carelessness, that we are almost inclined to believe that the poet either refused to submit to the trammels of a regular metre, or was unacquainted with the laws and rules of prosody. Yet of late a more minute examination of his writings, and a more profound study of the principles of Latin prosody and metrical laws, have led writers to take a different view of the subject. Many of the ancients bestowed unmeasured praise on the language of Plautus; yet we need not be surprised at the less favourable opinion pronounced by Horace, whose taste was formed upon a purer Greek model.

The earliest edition of Plautus is that of Venice, 1472; and the best is that published by Brunck, Bipont, 1788, in three vols. 8vo.

PLAYFAIR, John, a mathematician and philosopher of great eminence and celebrity; and so peculiarly a benefactor to this publication, as would have made it fit that some memorial of him should be preserved in these pages, even if it could have been surmised that it might not have been found in any other place. There are few names, however, in the recent history of British science that are more extensively or advantageously known, or of which the few particulars that remain to be recorded will be more generally interesting. His life, like most others that have been dedicated to the silent pursuits of learning and science, does not abound in incidents or adventures; but it is full of honour, both for the individual and the studies to which he was devoted, and may be read with more profit than many more ambitious histories.

He was the eldest son of the Reverend James Playfair, minister of Benvie, in Forfarshire; in which place he was born on the 10th of March 1748. He resided at home, under the domestic tuition of his father, until the age of fourteen, when he entered at the University of St Andrews; and was almost immediately distinguished, not merely for his singular proficiency in mathematical learning, but for the extent of his general knowledge, the clearness of his judgment, and the dignity and propriety of his conduct. A remarkable testimony to this effect has been made public in an early letter of Principal George Hill, who was at this time one of his fellow-students, and was himself so remarkable for early talent, that we find it recorded of him, that he had privately composed an excellent sermon in the tenth year of his age. A youth of this description cannot be supposed to have been very indulgent in his estimate of the merits of his competitors; and it could therefore have been no ordinary measure of ability that called forth the following ingenuous avowal, in a confidential letter to his mother: "Playfair has very great merit, and more knowledge and a better judgment than any of his class-fellows. I make *no* exceptions; my parts might be more showy, and the kind of reading to which my inclination led me was calculated to enable me to make a better figure at St Andrews; but in judgment and understanding I was greatly inferior to him."[1] It is scarcely a stronger, though undoubtedly a very different proof of his rare attainments, that when the professor of natural philosophy, Wilkie, the once celebrated author of the *Epigoniad*, was prevented by indisposition from delivering the regular lectures, he used generally to delegate the task of instruction to his youthful pupil. Wilkie, besides being a scholar and philosopher of no mean note, was a man of primitive benevolence and integrity, and of great vivacity in conversation; and the friendship which, in spite of the disparity of their years, was speedily formed between him and young Playfair, speaks as much for the social and moral character of the latter, as his substitution of him in the class-room does for his early proficiency in science. On this last subject we shall mention but one fact more. In 1766, when only eighteen years of age, he offered himself, with the approbation of his instructors at St Andrews, as candidate for the professorship of mathematics in Mareschal College, Aberdeen, and sustained, with the most distinguished credit, an examination or comparative trial, which lasted eleven days, and embraced nearly the whole range of the exact sciences. Out of the six competitors who entered the lists against him, two only were judged to have excelled him, the Reverend Dr Trail, who was appointed to the office, and Dr Hamilton, who afterwards succeeded to and long filled it with much reputation.

In 1769, he removed to Edinburgh, where his merit and modesty very soon introduced him to the friendship of Dr Robertson, Adam Smith, Dr Matthew Stewart, Dr Black, and Dr Hutton; with all of whom he continued on terms of the utmost cordiality during the whole period of their lives. In 1772, he was a candidate for the professorship of natural philosophy at St Andrews, vacant by the death of his friend Dr Wilkie. There was no comparative trial on this occasion; and he was again unsuccessful, under circumstances which have led one of the most dutiful sons of that university (Dr Cook, in his Life of Principal Hill) to remark, "how much it suffered in thus losing a man by whose talents its reputation would have been so highly promoted." In the course of the same year, the death of his father suddenly devolved upon him the burden of supporting the family, and admonished him no longer to delay the final election of a profession. He had been educated with a view to the church, and was every way qualified to accept a living on the establishment; but his decided predilection for science had hitherto made him hesitate about engaging in a vocation, the duties of which, he felt, if conscientiously discharged, would necessarily interfere, to a great extent, with the studies he was loth to abandon. In this emergency, however, he thought himself no longer entitled to indulge in those predilections, and accordingly made application to Lord Gray, the patron, for a presentation to the livings of Liff and Benvie, which had been filled by his father. His lordship was too well aware of his merits to hesitate about conferring so great a benefit on the parishioners; and immediately issued a presentation in his favour, although, from some challenge of his right to the patronage, induction was not obtained until late in the year 1773.

From this period until 1782 Mr Playfair was constantly resident at Liff, and occupied almost exclusively with the pastoral duties of his office. In this retreat his leisure hours were dedicated to the education of his younger brothers, and to a very close and intimate correspondence with Mr Robertson (afterwards Lord Robertson), the son of the illustrious historian, to whom he seems to have confined the remarks that occurred to him upon the different authors he perused, and the subjects of speculation which they suggested. We cannot help hoping, that some selection from this correspondence may one day be given to the public. In the year 1779, he contributed to the Transactions of the Royal Society of London a paper on the Arithmetic of Impossible Quantities, which exhibits, within a very small compass, a striking example of the rare and admirable talent of detaching the sound spirit of science from what may be termed its mysticism, and circumscribing, by the most precise and luminous boundaries, the vague and unlimited inquiries into which many mathematicians had been seduced by the nature of the instruments they employed.

In the year 1782 he was induced, by very advantageous offers, to resign his charge, and to superintend the education of Mr Ferguson of Raith, and his brother Sir Ronald; an arrangement which restored him, in a great measure, to the literary and scientific society of Edinburgh, and enabled him to gratify himself by a personal introduction to several of the most eminent cultivators of science in London. He had repeatedly visited Dr Maskelyne, astronomer royal, whilst that ingenious mathematician was busied, in 1774, in making a series of observations in Perthshire, on the attraction of mountains; and, whilst sharing the shelter of his tent on the side of Schehallien, contracted with him a cordial friendship, which continued unbroken for the remainder of their lives. Under these honourable auspices he made his first appearance in London in 1782, and was speedily introduced to all those in whom he was likely to take most interest. He seems to have kept a pretty full and correct journal of all that he observed during this journey to the metropolis; and a portion of it, which is prefixed to the late collection of his works, is, in our judgment, one of the most interesting parts of that publication. It is not only written with great elegance and accuracy, but affords, in the free, candid, and pointed observations which it contains on the different individuals with whom he comes in contact, a very remarkable proof of his quick and sagacious perception of character, and his power of selecting and turning to account, even in the fever and distraction of a first visit to such a scene, all that was really worthy of careful observation or permanent remembrance.

---

[1] Dr Cook's Life of Principal Hill.

In 1785 he was received into the University of Edinburgh, in consequence of an arrangement between his two illustrious associates, Dr Adam Ferguson and Mr Dugald Stewart. Mr Stewart exchanged the chair of mathematics, in which he had succeeded to his father, for that of moral philosophy, which had been long filled by Dr Ferguson; who, finding that the delicate state of his health would prevent him from discharging the active duties of the mathematical professor, immediately devolved them upon Mr Playfair, for whom he procured the appointment of joint professor in that department.

In 1788 he published, in the Transactions of the Royal Society of Edinburgh, a Biographical Account of Dr Matthew Stewart, which is remarkable, not only for the ease and purity of the style, but also as containing a singularly clear and interesting account of the labours of Dr Simson in the restoration of the ancient geometry, and of the success both of him and Dr Stewart in adapting the elegant simplicity of the Greek methods of investigation to problems which had previously been regarded as insoluble except by the aid of the modern analysis. He also published, in the same year, a paper on the Causes which affect the Accuracy of Barometrical Measurements, which is written with all the perspicuity, caution, and sagacity that constitute the great excellence and the great difficulty of such disquisitions, where scientific principles are employed to give precision to physical observations.

In 1790 he published in the same Transactions a paper of still greater interest and delicacy, on the Astronomy of the Brahmins; a subject which had been recently recommended to the notice of the European scientific world by the curious and learned observations of M. Bailly, in his General History of Astronomy, but had never met with so minute and scrupulous an investigation as it now received at the hands of Mr Playfair. The whole treatise is written with a beautiful perspicuity, in an admirable spirit of candour and ingenuity, and in a style more elegant and spirited than had yet lent its attraction to subjects so recondite and abstruse. The publication accordingly attracted very general notice, both in Europe and in Asia; and gave rise to much discussion and research, the final value and result of which does not seem yet to be ascertained. This was followed in 1794 by a learned and very beautiful treatise on the Origin and Investigation of Porisms, in which the obscure nature of the very comprehensive and indefinite theorems to which this name was applied by the ancient geometers, is explained with the most lucid simplicity; and the extraordinary merits of Dr Simson, in deducing their true theory from the very vague and scanty notices of them which had come down to his time, are commemorated with a noble spirit of emulation.

In 1795 he published his Elements of Geometry, for the use of the pupils attending his class; a work which has since been held in such estimation by the public, as to have gone through five editions of a thousand copies each, four of which were called for since the work ceased to be used as a class-book in the University of Edinburgh. In 1797 he composed a sequel to his first paper on the Indian Astronomy, in the shape of Observations on the Trigonometrical Tables of the Brahmins; and also a masterly collection of Theorms on the Figure of the Earth. It is also understood that he occupied himself a good deal at this time in the preparation of an Essay on the Accidental Discoveries made by Men of Science while in Pursuit of some other Object; although we find no portion of this curious discussion in the collection of his works.

His excellent and ingenious friend Dr Hutton died in the year last mentioned; and Mr Playfair, having undertaken to draw up a biographical account of him for the Royal Society, was first led to study his ingenious but somewhat crude speculations on the Theory of the Earth, and afterwards to lend them the assistance of his own powerful pen in his Illustrations of the Huttonian Theory. This work, upon which he bestowed more time and labour than on any of his other productions, did not appear till 1802; and it was not till 1803 that he presented to their associates his admirable memoir of their departed friend.

Whatever opinion may be formed, now or hereafter, of the truth or soundness of the suppositions by which Dr Hutton endeavoured to explain the actual state and condition of our globe, it is impossible to doubt that Mr Playfair's illustration of that theory must always be ranked amongst the most brilliant and powerful productions of philosophical genius. The beautiful clearness and captivating eloquence with which the system itself is unfolded and explained, the spirit and force of reasoning with which all the objections to it are combated, the skill with which the infinite variety of facts which it brought into view are combined into one grand and legitimate introduction, and the judgment and extent of learning by which so many large and profound views of nature are brought to bear upon the points in discussion, and blended into one large and discursive argument, uniting the utmost logical precision with the richest variety of topics, and the highest graces of composition—are merits which have been universally acknowledged in this performance, even by those who have not been convinced by its reasonings, and have extorted, even from the fastidious critics of France, the acknowledgment that "Mr Playfair writes as well as Buffon, and reasons incomparably better."

The biographical account of Dr Hutton is by far the best of Mr Playfair's productions in this line, and contains not only an eloquent and luminous account of the speculations in which he was engaged, but, what is too often forgotten in this species of biography, a charming portrait of the individual, drawn, no doubt, by a favourable hand, but gaining far more in grace and effect than it can possibly have lost in correctness, from the softening colours of affection.

In 1805 he quitted the chair of mathematics to succeed Professor Robison in that of natural philosophy. The appointment of Mr Leslie as his successor in the chair of mathematics was opposed at the time by a majority of the presbytery of Edinburgh, and made the subject of very angry discussion, as well in various publications as in the General Assembly of the Church of Scotland. From both these fields of contention the opponents of Mr Leslie retired discomfited, and, in the opinion, we believe, of many of the lookers on, disgraced. Amongst the heaviest blows they had to sustain were those that parted from the hand of Mr Playfair. He first addressed a Letter to the Lord Provost, in which, after asserting, with infinite spirit and freedom, the dignity of the science in question, he openly imputes the new-sprung zeal for orthodoxy, which had prompted the attack on Mr Leslie, to a wish or design on the part of some of the clergymen of Edinburgh to obtain for themselves a number of the chairs in that university, which had hitherto afforded sufficient occupation to the undistracted industry of laymen: And when this denunciation brought upon him a series of acrimonious and unhandsome attacks, he replied to them all in a pamphlet of greater bulk, written in a style of which the high polish and elegance only serve to give a keener edge to the unsparing severity of the exposures which it conveys.[1] We do not know, indeed, where to find a more perfect model of polemical or controversial writing; and, much as it was to be regretted that an occasion should have arisen for employing such a pen and such a mind as Mr Playfair's on any temporary or personal theme, it is impossible not to admire the extraordinary talent and vigour with which, when the occasion did arrive, he could turn talents, exercised in far other studies, to the purposes suggested by the emergency.

In 1807 he was elected a fellow of the Royal Society of London, and soon afterwards presented to that learned body his Lithological Survey of Schehallien. In 1809 he contributed to the Edinburgh Transactions an excellent paper on Solids of the greatest Attraction, and in 1812 another on the Progress of Heat in Spherical Bodies.

In 1814 he published, in two volumes 8vo, for the use of his class, an elementary work of great value, under the title of Outlines of Natural Philosophy. For some years before this, he had been much occupied in digesting the plan and collecting the materials for a greatly enlarged edition of his Illustrations of the Huttonian Theory; with a view to which, he had not only carefully perused and extracted a vast body of voyages and travels, but had made various journeys, and very minutely examined almost all the places in the British dominions the structure of which promised to throw any light on the subject of his researches. No part of the work, however, was actually written, when the preparation for it was suspended by his being induced to draw up for this publication an introductory Dissertation on the Progress of Mathematical and Physical Science; a treatise which, though its author had written nothing else, would itself suffice to carry down his name with distinction to the latest posterity. The soundness of judgment, the beauty of the writing, the extent of knowledge, the candour and precision of the estimates of character, and the noble spirit of liberality and generous admiration for genius which breathes throughout the whole performance, give it an attraction which is rarely to be found in works of the same erudition, and render it not only one of the most instructive, but one of the most interesting publications that philosophy has ever bestowed on the world.

In 1815 he drew up for the Royal Society of Edinburgh a very interesting Memoir of his distinguished predecessor Dr John Robison, a philosopher in whose early life there was more adventure, and in his later days more political prejudice, than we usually find to diversify the history of men of science. Nothing can be more spirited and interesting than Mr Playfair's account of the former; nothing more manly and tender than his reluctant but decided protestation against the excesses of the latter.

After the general peace in 1815 had at last opened the Continent to British inquirers, Mr Playfair, at the age of sixty-eight, undertook a long journey through France and Switzerland into Italy, and did not return for a period of nearly eighteen months. His principal attention was directed to the mineralogical and geological phenomena of the different regions which he visited; and he made many notes with a view to the great object which he was not destined to accomplish, namely, the extension and new-modelling of his Illustrations of the Huttonian Theory. Every object of liberal curiosity, however, had for him an attraction as fresh as in his earliest youth; and the social simplicity and benevolence of his character and manners insured him a favourable reception in every new society to which he was introduced.

On his return from this expedition, he employed himself chiefly in preparing the Second Part of the Dissertation to which we have alluded; and he also drew up a Memoir on the Naval Tactics of Mr Clerk of Eldin, which was published after his death in the Philosophical Transactions, though only a fragment of a projected life of Mr Clerk, which he did not live to complete. His health had been occasionally broken for several years by the recurrence of a painful affection of the bladder, which appeared with increased severity in the early part of 1819, but was so far got under as to enable him to complete his course of lectures in the spring. It returned, however, in a still more distressing form in the summer, and at last put a period to his life on the 19th of July. Though suffering great pain during the last part of his confinement, he retained not only his intellectual faculties quite unimpaired, but also the serenity and mildness of his spirit, and occupied himself till within a few days of his death in correcting the proof-sheets of the Dissertation, the printing of the Second Part of which had commenced some time before his last illness.[2]

Before concluding these notices of Mr Playfair's scientific and literary labours, we have still to mention, that, from the year 1804, he was a frequent contributor to the Edinburgh Review; and that though most of his articles were of a scientific description, he occasionally diverged into the field of general literature, or indulged in the refinements of metaphysical speculation. Many of his scientific articles attracted great attention on the Continent as well as at home; and several of them are written with a force and beauty that might well entitle them to a higher place than the pages of a periodical publication. There is no general account of the great facts and principles of astronomy so clear, and comprehensive, and exact, nor half so beautiful or majestic in the writing, as his account of Laplace's *Mécanique Céleste*, in the eleventh volume of the publication just mentioned.

In this brief sketch of the events of Mr Playfair's life, we have purposely omitted any general account, either of his personal character, or of the distinguishing features of his intellectual powers and habits; thinking it better to give those by themselves, in the words in which they were recorded, to the satisfaction, we believe, of most of those who knew him intimately, in a periodical journal wherein they appeared a short time after his death. The portrait there given has been pronounced by one of the earliest and most illustrious of his surviving friends, "a faithful and perfect resemblance;"[3] and has accordingly been allowed a place in the prefatory memoir which his nephew has prefixed to the collection of his works.

"It has struck many people, we believe, as very extraordinary, that so eminent a person as Mr Playfair should have been allowed to sink into his grave in the midst of us, without calling forth almost so much as an attempt to commemorate his merit, even in a common newspaper; and that the death of a man so celebrated and so beloved, and, at the same time, so closely connected with many who could well appreciate and suitably describe his excellencies, should be left to the brief and ordinary notice of the daily obituary. No event of the kind certainly ever excited more general sympathy; and no individual, we are persuaded, will be longer or more affectionately remembered by all the classes of his fellow-citizens; and yet it is to these very circumstances that we must look for an explanation of the apparent neglect by which his memory has been followed. His humbler admirers have been deterred from expressing their sentiments by a natural feeling of unwillingness to encroach on the privilege of those whom a nearer approach to his person and talents rendered it more worthy to speak of them; whilst the learned and eloquent amongst his friends have trusted to each other for the performance of a task which they could not but feel to be painful in itself, and not a little difficult to perform as it ought to be; or perhaps have reserved for some more solemn occasion that tribute for which the public impatience is already at its height.

[1] This piece is entitled Letter to the Author of the Examination of Mr Stewart's Short Statement of Facts relative to the Election of Professor Leslie, 8vo, Edin. 1806. It has not been reprinted in the collection of his works.

[2] Besides the DISSERTATION, Mr Playfair contributed the valuable biographical account of ÆPINUS, and the still more valuable article on PHYSICAL ASTRONOMY.

[3] Letter from Mr Dugald Stewart to Dr Playfair, in the Appendix to the Biographical Account of Professor Playfair, prefixed to the collection of his works, published at Edinburgh in 1822, in 4 vols. 8vo.

"We beg leave to assure our readers, that it is merely from anxiety to do *something* to gratify this natural impatience that we presume to enter at all upon a subject to which we are perfectly aware that we are incapable of doing justice; for of Mr Playfair's scientific attainments, of his proficiency in those studies to which he was peculiarly devoted, we are but slenderly qualified to judge. But we believe we hazard nothing in saying that he was one of the most learned mathematicians of his age, and among the first, if not the very first, who introduced the beautiful discoveries of the later continental geometers to the knowledge of his countrymen; and gave their just value and true place, in the scheme of European knowledge, to those important improvements by which the whole aspect of the abstract sciences has been renovated since the days of our illustrious Newton. If he did not signalize himself by any brilliant or original invention, he must, at least, be allowed to have been a most generous and intelligent judge of the achievements of others; as well as the most eloquent expounder of that great and magnificent system of knowledge which has been gradually evolved by the successive labours of so many gifted individuals. He possessed, indeed, in the highest degree, all the characteristics both of a fine and a powerful understanding; at once penetrating and vigilant, but more distinguished, perhaps, for the caution and sureness of its march, than for the brilliancy or rapidity of its movements; and guided and adorned through all its progress by the most genuine enthusiasm for all that is grand, and the justest taste for all that is beautiful, in the truth or the intellectual energy with which he was habitually conversant.

"To what account these rare qualities might have been turned, and what more brilliant or lasting fruits they might have produced, if his whole life had been dedicated to the solitary cultivation of science, it is not for us to conjecture; but it cannot be doubted that they added incalculably to his eminence and utility as a teacher, both by enabling him to direct his pupils to the most simple and luminous methods of inquiry, and to imbue their minds, from the very commencement of the study, with that fine relish for the truths it disclosed, and that high sense of the majesty with which they were invested, that predominated in his own bosom. Whilst he left nothing unexplained or unreduced to its proper place in the system, he took care that they should never be perplexed by petty difficulties, or bewildered in useless details, and formed them betimes to that clear, masculine, and direct method of investigation by which, with the least labour, the greatest advances might be accomplished.

"Mr Playfair, however, was not merely a teacher; and has fortunately left behind him a variety of works, from which other generations may be enabled to judge of some of those qualifications which so powerfully recommended and endeared him to his contemporaries. It is, perhaps, to be regretted that so much of his time, and so large a proportion of his publications, should have been devoted to the subjects of the Indian Astronomy, and the Huttonian Theory of the Earth. For though nothing can be more beautiful or instructive than his speculations on those curious topics, it cannot be dissembled that their results are less conclusive and satisfactory than might have been desired; and that his doctrines, from the very nature of the subjects, are more questionable than we believe they could possibly have been on any other topic in the whole circle of the sciences. To the first, indeed, he came under the great disadvantage of being unacquainted with the eastern tongues, and without the means of judging of the authenticity of the documents which he was obliged to assume as the elements of his reasonings; and as to the other, though he ended, we believe, with being a very able and skilful mineralogist, we think it is now generally admitted that that science does not yet afford sufficient materials for any positive conclusion, and that all attempts to establish a theory of the earth must, for many years to come, be regarded as premature. Though it is impossible, therefore, to think too highly of the ingenuity, the vigour, and the eloquence of those publications, we are of opinion that a juster estimate of Mr Playfair's talent, and a truer picture of his genius and understanding, is to be found in his other writings; in the papers, both biographical and scientific, with which he has enriched the Transactions of our Royal Society; his account of Laplace, and other articles which he is understood to have contributed to the Edinburgh Review; the Outlines of his Lectures on Natural Philosophy; and, above all, his Introductory Discourse to the Supplement to the Encyclopædia Britannica, with the final correction of which he was occupied up to the last moments that the progress of his disease allowed him to dedicate to any intellectual exertion.

"With reference to these works, we do not think we are influenced by any national, or other partiality, when we say that he was certainly one of the best writers of his age; and even that we do not now recollect any one of his contemporaries who was so great a master of composition. There is a certain mellowness and richness about his style, which adorns without disguising the weight and nervousness, which is its other great characteristic; a sedate gracefulness and manly simplicity in the more level passages, and a mild majesty and considerate enthusiasm where he rises above them, of which we scarcely know where to find any other example. There is great equability, too, and sustained force, in every part of his writings. He never exhausts himself in flashes and epigrams, nor languishes into tameness and insipidity; at first sight you would say that plainness and good sense were the predominating qualities, but by and by this simplicity is enriched with the delicate and vivid colours of a fine imagination, the free and forcible touches of a most powerful intellect, and the lights and shaeds of an unerring and harmonizing taste. In comparing it with the styles of his most celebrated contemporaries, we would say that it was more purely and peculiarly a *written* style, and, therefore, rejected those ornaments that more properly belong to oratory. It had no impetuosity, hurry, or vehemence,—no bursts or sudden turns or abruptions, like that of Burke; and though eminently smooth and melodious, it was not modulated to an uniform system of solemn declamation like that of Johnson; nor spread out in the richer and more voluminous elocution of Stewart; nor still less broken into that patchwork of scholastic pedantry and conversational smartness which has found its admirers in Gibbon. It is a style, in short, of great freedom, force, and beauty; but the deliberate style of a man of thought and of learning, and neither that of a wit throwing out his extempores with an affectation of careless grace, nor of a rhetorician thinking more of his manner than his matter, and determined to be admired for his expression, whatever may be the fate of his sentiments.

"His habits of composition, as we have understood, were not perhaps exactly what might have been expected from their results. He wrote rather slowly, and his first sketches were often very slight and imperfect, like the rude chalking for a masterly picture. His chief effort and greatest pleasure was in their revisal and correction; and there were no limits to the improvement which resulted from this application. It was not the style merely, or indeed chiefly, that gained by it; the whole reasoning, and sentiment, and illustration, were enlarged and new-modelled in the course of it, and a naked outline became gradually informed with life, colour, and expression, It was not at all like the common finishing and polishing to which careful authors generally subject the first draught of their compositions, nor even like the fastidious and tentative alterations with which some more anxious writers assay their choicer passages. It was, in fact, the great filling in of the picture, the working up of the figured *weft* on the naked and meagre *woof* that had been stretched to receive it; and the singular thing in his case was, not only that he left this most material part of his work to be performed after the whole outline had been finished, but that he could proceed with it to an indefinite extent, and enrich and improve as long as he thought fit, without any risk either of destroying the proportions of that outline, or injuring the harmony and unity of the design. He was perfectly aware, too, of the possession of this extraordinary power; and it was partly, we presume, in consequence of this consciousness that he was not only at all times ready to go on with any work in which he was engaged, without waiting for favourable moments or hours of greater alacrity, but that he never felt any of those doubts and misgivings as to his being able to get creditably through with his undertaking, to which we believe most authors are occasionally liable. As he never wrote upon any subject of which he was not perfectly master, he was secure against all blunders in the substance of what he had to say; and felt quite assured, that if he was only allowed time enough, he should finally come to say it in the very best way of which he was capable. He had no anxiety, therefore, either in undertaking or proceeding with his tasks; and intermitted and resumed them at his convenience, with the comfortable certainty, that all the time he bestowed on them was turned to good account, and that what was left imperfect at one sitting might be finished with equal ease and advantage at another. Being thus perfectly sure both of his end and his means, he experienced, in the course of his compositions, none of that little fever of the spirits with which that operation is so apt to be accompanied. He had no capricious visitings of fancy, which it was necessary to fix upon the spot or to lose for ever; no casual inspiration to invoke and to wait for; no transitory and evanescent lights to catch before they faded. All that was in his mind was subject to his control, and amenable to his call, though it might not obey at the moment; and whilst his taste was so sure, that he was in no danger of overworking anything that he had designed, all his thoughts and sentiments had that unity and congruity, that they fell almost spontaneously into harmony and order; and the last added, incorporated, and assimilated with the first, as if they had sprung simultaneously from the same happy conception.

“ But we need dwell no longer on qualities that may be gathered hereafter from the works he has left behind him. They who lived with him mourn the most for those which will be traced in no such memorial; and prize far above those talents which gained him his high name in philosophy, that personal character which endeared him to his friends, and shed a grace and a dignity over all the society in which he moved. The same admirable taste which is conspicuous in his writings, or rather the higher principles from which that taste was but an emanation, spread a similar charm over his whole life and conversation, and gave to the most learned philosopher of his day the manners and deportment of the most perfect gentleman. Nor was this in him the result merely of good sense and good temper, assisted by an early familiarity with good company, and a consequent knowledge of his own place and that of all around him. His good breeding was of a higher descent; and his powers of pleasing rested on something better than mere companionable qualities. With the greatest kindness and generosity of nature, he united the most manly firmness, and the highest principles of honour; and the most cheerful and social dispositions, with the gentlest and steadiest affections. Towards women he had always the most chivalrous feelings of regard and attention, and was, beyond almost all men, acceptable and agreeable in their society, though without the least levity or pretension unbecoming his age or condition; and such, indeed, was the fascination of the perfect simplicity and mildness of his manners, that the same tone and deportment seemed equally appropriate in all societies, and enabled him to delight the young and the gay with the same sort of conversation which instructed the learned and the grave. There never, indeed, was a man of learning and talent who appeared in society so perfectly free from all sorts of pretension or notion of his own importance, or so little solicitous to distinguish himself, or so sincerely willing to give place to every one else. Even upon subjects which he had thoroughly studied, he was never in the least impatient to speak, and spoke at all times without any tone of authority; whilst, so far from wishing to set off what he had to say by any brilliancy or emphasis of expression, it seemed generally as if he had studied to disguise the weight and originality of his thoughts under the plainest form of speech and the most quiet and indifferent manner; so that the profoundest remarks and subtlest observations were often dropped, not only without any solicitude that their value should be observed, but without any apparent consciousness that they possessed any. Though the most social of human beings, and the most disposed to encourage and sympathise with the gaiety and joviality of others, his own spirits were in general rather cheerful than gay, or at least never rose to any turbulence or tumult of merriment; and whilst he would listen with the kindest indulgence to the more extravagant sallies of his younger friends, and prompt them by the heartiest approbation, his own satisfaction might generally be traced in a slow and temperate smile, gradually mantling over his benevolent and intelligent features, and lighting up the countenance of the sage with the expression of the mildest and most genuine philanthropy. It was wonderful, indeed, considering the measure of his own intellect, and the rigid and undeviating propriety of his own conduct, how tolerant he was of the defects and errors of other men. He was too indulgent, in truth, and favourable to his friends, and made a kind and liberal allowance for the faults of all mankind; except only faults of baseness or of cruelty, against which he never failed to manifest the most open scorn and detestation. Independently, in short, of his high attainments, Mr Playfair was one of the most amiable and estimable of men; delightful in his manners, inflexible in his principles, and generous in his affections, he had all that could charm in society or attach in private; and whilst his friends enjoyed the free and unstudied conversation of an easy and intelligent associate, they had at all times the proud and inward assurance that he was a being upon whose perfect honour and generosity they might rely with the most implicit confidence, in life and in death,—and of whom it was equally impossible that, under any circumstances, he should ever perform a mean, a selfish, or a *questionable* action, as that his body should cease to gravitate or his soul to live.

“ If we do not greatly deceive ourselves, there is nothing here of exaggeration or partial feeling, and nothing with which an indifferent and honest chronicler would not concur. Nor is it altogether idle to have dwelt so long on the personal character of this distinguished individual. For we are ourselves persuaded, that this personal character has done almost as much for the cause of science and philosophy amongst us as the great talents and attainments with which it was combined; and has contributed in a very eminent degree to give to the better society of Edinburgh that tone of intelligence and liberality by which it is so honourably distinguished. It is not a little advantageous to philosophy that it is in fashion; and it is still more advantageous, perhaps, to the society which is led to confer on it this apparently trivial distinction. It is a great thing for the country at large,—for its happiness, its prosperity, and its renown,—that the upper and influencing part of its population should be made familiar, even in its untasked and social hours, with sound and liberal information, and be taught to know and respect those who have distinguished themselves for great intellectual attainments. Nor is it, after all, a slight or despicable reward for a man of genius to be received with honour in the highest and most elegant society around him, and to receive in his living person that homage and applause which is too often reserved for his memory. Now, those desirable ends can never be effectually accomplished, unless the manners of our leading philosophers are agreeable, and their personal habits and dispositions engaging and amiable. From the time of Hume and Robertson, we have been fortunate in Edinburgh in possessing a succession of distinguished men, who have kept up this salutary connection between the learned and the fashionable world; but there never, perhaps, was any one who contributed so powerfully to confirm and extend it, and that in times when it was peculiarly difficult, as the lamented individual of whom we are now speaking; and they who have had the best opportunity to observe how superior the society of Edinburgh is to that of most other places of the same size, and how much of that superiority is owing to the cordial combination of the two aristocracies of rank and of letters (of both of which it happens to be the chief provincial seat), will be best able to judge of the importance of the service he has thus rendered to its inhabitants, and through them, and by their example, to all the rest of the country." (P. P.)

PLAYHOUSE. The most ancient English playhouses were the Curtain in Shoreditch, and the Theatre. In the time of Shakspeare, who commenced dramatic writer in 1592, there were no less than ten theatres open. Four of these were private houses, namely, that in Blackfriars, the Cockpit or Phœnix in Drury-Lane, a theatre in Whitefriars, and one in Salisbury Court. The other six were called public theatres, namely, the Globe, the Swan, the Rose, and the Hope, on the Bank-side; the Red Bull, at the upper end of St John's Street; and the Fortune in White-Cross Street. The two last were chiefly frequented by citizens. Mr Malone gives a pretty copious account of these playhouses, in a supplement to his last edition of Shakspeare, which account we shall here insert.

"Most, if not all," says he, "of Shakspeare's plays were performed either at the Globe, or at the Theatre in Blackfriars. It appears that they both belonged to the same company of comedians, viz. his majesty's servants, which title they assumed, after a license had been granted to them by King James in 1603, having before that time been called the servants of the lord chamberlain.

"The theatre in Blackfriars was a private house; but the peculiar and distinguishing marks of a private playhouse it is not easy to ascertain. It was very small, and plays were there usually represented by candle-light. The Globe, situated on the southern side of the river Thames, was a hexagonal building, partly open to the weather, partly covered with reeds. It was a public theatre, and of considerable size, and there they always acted by daylight. On the roof of the Globe, and the other public theatres, a pole was erected, to which a flag was affixed. These flags were probably displayed only during the hours of exhibition; and it should seem, from a passage in one of the old comedies, that they were taken down during Lent, in which season no plays were presented. The Globe, though hexagonal at the outside, was probably a rotunda within, and perhaps had its name from its circular form. It might, however, have been denominated only from its sign, which was a figure of Hercules supporting the Globe. This theatre was burnt down in 1613, but it was rebuilt in the following year, and decorated with more ornament than had been originally bestowed upon it. The exhibitions at the Globe seem to have been calculated chiefly for the lower class of people; those at Blackfriars for a more select and judicious audience.

"A writer informs us, that one of these theatres was a winter and the other a summer house. As the Globe was partly exposed to the weather, and they acted there usually by daylight, it was probably the summer theatre. The exhibitions here seem to have been more frequent than at Blackfriars, at least till the year 1604 or 1605, when the Bank-side appears to have become less fashionable and less frequented than it formerly had been. Many of our ancient dramatic pieces were performed in the yards of carriers' inns; in which, in the beginning of Queen Elizabeth's reign, the comedians, who then first united themselves in companies, erected an occasional stage. The form of these temporary playhouses seems to be preserved in our modern theatre. The galleries are in both ranged over each other on three sides of the building. The small rooms under the lowest of these galleries answer to our present boxes; and it is observable that these, even in theatres which were built in a subsequent period expressly for dramatic exhibitions, still retained their old name, and are frequently called rooms by our ancient writers. The yard bears a sufficient resemblance to the pit as at present in use. We may suppose the stage to have been raised in this area, on the fourth side, with its back to the gate-way of the inn, at which the money for admission was taken. Hence, in the middle of the Globe, and I suppose of the other public theatres, in the time of Shakspeare, there was an open yard or area, where the common people stood to see the exhibition; from which circumstance they are called by our author groundlings, and by Ben Johnson 'the understanding gentlemen of the ground.'

"In the ancient playhouses there appears to have been a private box, of which it is not easy to ascertain the situation. It seems to have been placed at the side of the stage, towards the rear, and to have been at a lower price; in this some people sat, either from economy or singularity. The galleries, or scaffolds as they are sometimes called, and that part of the house which in private theatres was named the pit, seem to have been at the same price; and probably in houses of reputation, such as the Globe, and that in Blackfriars, the price of admission into those parts of the theatres was sixpence, while in some meaner playhouses it was only one penny, in others only twopence. The price of admission into the best rooms or boxes was, I believe, in our author's time, one shilling; though afterwards it appears to have risen to two shillings and half-a-crown.

"From several passages in our old plays, we learn, that spectators were admitted on the stage, and that the critics and wits of the time usually sat there. Some were placed on the ground; others sat on stools, of which the price was either sixpence or one shilling, according, I suppose, to the commodiousness of the situation; and they were attended by pages, who furnished them with pipes and tobacco, which was smoked here as well as in other parts of the house; yet it should seem that persons were suffered to sit on the stage only in the private playhouses, such as Blackfriars, &c. where the audience was more select, and of a higher class; and that in the Globe and other public theatres no such licence was permitted.

"The stage was strewed with rushes, which, as we learn from Hentzner and Caius de Ephemera, was, in the time of Shakspeare, the usual covering of floors in England. The curtain which hangs in the front of the present stage, drawn up by lines and pulleys, though not a modern invention, for it was used by Inigo Jones in the masks at court, was yet an apparatus to which the simple mechanism of our ancient theatres had not arrived, for in them the curtains opened in the middle, and were drawn backwards and forwards on an iron rod. In some playhouses they were woollen, in others made of silk. Towards the rear of the stage there appears to have been a balcony, the platform of which was probably eight or ten feet from the ground. I suppose it to have been supported by pillars. From hence, in many of our old plays, part of the dialogue was spoken; and in the front of this balcony curtains likewise were hung.

"A doubt has been entertained whether, in our ancient theatres, there were side and other scenes. The question is involved in so much obscurity, that it is very difficult to form any decided opinion upon it. It is certain, that in the year 1695 Inigo Jones exhibited an entertainment at Oxford, in which moveable scenes were used; but he appears to have introduced several pieces of machinery in the masks at court, with which undoubtedly the public theatres were unacquainted. A passage which has been produced from one of the old comedies proves, it must be owned, that even these were furnished with some pieces of machinery, which were used when it was requisite to exhibit the descent of some god or saint; but, from all the contemporary accounts, I am inclined to believe that the mechanism of our ancient stage seldom went beyond a painted chair or a trap-door, and that few, if any of them, had any moveable scenes. When King Henry VIII. is to be discovered by the Dukes of Suffolk and Norfolk, reading in his study, the scenical direction in the first folio, 1623, which was printed apparently from playhouse copies, is 'the king draws the curtain (*i. e.* draws it open), and sits reading pensively;' for, besides the principal curtains that hung in the front of the stage, they used others as substitutes for scenes. If a bedchamber is to be exhibited, no change of scene is mentioned; but the property-man is simply ordered to thrust forth a bed. When the fable requires the Roman capitol to be exhibited, we find two officers enter, 'to lay cushions, as it were, in the capitol,' &c. On the whole, it appears, that our ancient theatres in general were only furnished with curtains, and a single scene composed of tapestry, which were sometimes, perhaps, ornamented with pictures; and some passages in our old dramas incline one to think, that when tragedies were performed the stage was hung with black.

"In the early part, at least, of our author's (Shakspeare's) acquaintance with the theatre, the want of scenery seems to have been supplied by the simple expedient of writing the names of the different places where the scene was laid in the progress of the play, which were disposed in such a manner as to be visible to the audience. The invention of trap-doors, however, appears not to be modern; for in an old Morality, entitled All for Money, we find a marginal direction which implies that they were very early in use. The covering or internal roof of the stage was anciently termed the heavens. It was probably painted of a sky-blue colour, or perhaps pieces of drapery tinged with blue were suspended across the stage to represent the heavens.

"It is probable that the stage was formerly lighted by two large branches, of a form similar to those now hung in churches. They gave place in a subsequent period to small circular wooden frames, furnished with candles, eight of which were hung on the stage, four at either side; and these within a few years were wholly removed by Mr Garrick, who, on his return from France, first introduced the present commodious method of illuminating the stage by lights not visible to the audience. Many of the companies of players were formerly so thin, that one person played two or three parts; and a battle on which the fate of an empire was supposed to depend was decided by half a dozen combatants. It appears to have been a common practice in their mock engagements to discharge small pieces of ordnance on the stage. Before the exhibition began, three flourishes or pieces of music were played, or, in the ancient language, there were three soundings. Music was likewise played between the acts. The instruments chiefly used were trumpets, cornets, and hautboys. The band, which did not consist of more than five or six performers, sat in an upper balcony, over what is now called the stage-box.

"The person who spoke the prologue was ushered in by trumpets, and usually wore a long black velvet cloak, which, I suppose, was considered as best suited to a supplicatory address. Of this custom, whatever might have been its origin, some traces remained till very lately, a black coat having been, if I mistake not, within these few years the constant stage habiliment of our modern prologue speakers. The dress of the ancient prologue speaker is still retained in the play that is exhibited in Hamlet before the king and court of Denmark. The performers of male characters generally wore periwigs, which in the age of Shakspeare were not in common use. It appears from a passage in Puttenham's Art of English Poesy, 1589, that vizards were on some occasions used by the actors of those days; and it may be inferred, from a scene in one of our author's comedies, that they were sometimes worn in his time by those who performed female characters; but this I imagine was very rare. Some of the female part of the audience likewise appeared in masks. The stage-dresses, it is reasonable to suppose, were much more costly at some theatres than at others; yet the wardrobe of even the king's servants at the Globe and Blackfriars was, we find, but scantily furnished; and our author's dramas derived very little aid from the splendour of exhibition.

"It is well known, that in the time of Shakspeare, and for many years afterwards, female characters were represented by boys or young men. Sir William d'Avenant, in imitation of the foreign theatres, first introduced females in the scene, and Mrs Betterton is said to have been the first woman that appeared on the English stage. Andrew Pennycuike played the part of Matilda in a tragedy of Davenport's, in 1655; and Mr Kynaston acted several female parts after the Restoration. Downes, a contemporary of his, assures us, 'that being then very young, he made a complete stage beauty, performing his parts so well, particularly Arthiope and Aglaura, that it has since been disputable among the judicious whether any woman that succeeded him touched the audience so sensibly as he.'

"Both the prompter, or book-holder as he was sometimes called, and the property-man, appear to have been regular appendages of our ancient theatres. No writer that I have met with intimates, that in the time of Shakspeare it was customary to exhibit more than a single dramatic piece in one day. The Yorkshire tragedy, or All's One, indeed, appears to have been one of four pieces that were represented on the same day; and Fletcher has also a piece called Four Plays in One; but probably these were either exhibited on some particular occasion, or were ineffectual efforts to introduce a new species of amusement; for we do not find any other instances of the same kind. Had any shorter pieces been exhibited after the principal performance, some of them probably would have been printed; but there are none extant of an earlier date than the time of the Restoration. The practice, therefore, of exhibiting two dramas successively in the same evening, we may be assured was not established before that period. But though the audiences in the time of our author were not gratified by the representation of more than one drama in the same day, the entertainment was diversified, and the populace diverted, by vaulting, tumbling, slight of hand, and morris-dancing, a mixture not much more heterogeneous than that with which we are daily presented, a tragedy and a farce.

"The amusements of our ancestors, before the commencement of the play, were of various kinds, such as reading, playing cards, drinking ale, or smoking tobacco. It was a common practice to carry table-books to the theatre, and, either from curiosity or enmity to the author, or some other motive, to write down passages of the play that was represented; and there is reason to believe that the imperfect and mutilated copies of some of Shakspeare's dramas, which are yet extant, were taken down in short-hand during the exhibition. At the end of the piece, the actors, in noblemen's houses and in taverns, where plays were frequently performed, prayed for the health and prosperity of their patrons; and in the public theatres for the king and queen. This prayer sometimes made part of the epilogue. Hence, probably, as Mr Steevens has observed, the addition of *Vivant rex et regina* to the modern play-bills.

"Plays, in the time of our author, began at one o'clock in the afternoon; and the exhibition was usually finished in two hours. Even in 1667 they commenced at three. When Gosson wrote his School of Abuse, in 1579, it seems the dramatic entertainments were usually exhibited on Sundays. Afterwards they were performed on that and other days indiscriminately. It appears from a contemporary writer, that exhibiting plays on Sunday had not been abolished in the third year of King Charles I.

"The modes of conveyance to the theatre, anciently as at present, seem to have been various; some going in coaches, others on horseback, and many by water. To the Globe playhouse the company probably were conveyed by water; to that in Blackfriars the gentry went either in coaches or on horseback, and the common people on foot. In an epigram to Sir John Davis, the practice of riding to the theatre is ridiculed as a piece of affectation or vanity, and therefore we may presume it was not very general.

"The long and whimsical titles that are prefixed to the quarto copies of our author's plays, I suppose to have been transcribed from the play-bills of the time. A contemporary writer has preserved something like a play-bill of those days, which seems to corroborate this observation; for if it were divested of rhime, it would bear no very distant resemblance to the title-pages that stand before some of our author's dramas:

> Prithee, what's the play?
> (The first I visited this twelvemonth day)
> They say, "A new invented play of Purle,
> That jeoparded his neck to steal a girl
> Of twelve; and lying fast inpounded for't,
> Has hither sent his beard to act his part;
> Against all those in open malice bent,
> That would not freely to the theft consent:
> Feigns all to's wish, and in the epilogue
> Goes out applauded for a famous rogue"
> —Now hang me if I did not look at first
> For some such stuff, by the fond people's thrust.

"It is uncertain at what time the usage of giving authors a benefit on the third day of the exhibition of their pieces commenced. Mr Oldys, in one of his manuscripts, intimates that dramatic poets had anciently their benefit on the first day that a new play was represented; a regulation which would have been very favourable to some of the ephemeral productions of modern times. But for this there is not, I believe, any sufficient authority. From D'Avenant, indeed, we learn, that in the latter part of the reign of Queen Elizabeth the poet had his benefit on the second day. As it was a general practice in the time of Shakspeare to sell the copy of the play to the theatre, I imagine in such cases an author derived no other advantage from his piece than what arose from the sale of it. Sometimes, however, he found it more beneficial to retain the copyright in his own hands; and when he did so, I suppose he had a benefit. It is certain that the giving authors the profit of the third exhibition of their play, which seems to have been the usual mode during almost the whole of the last century, was an established custom in the year 1612; for Decker, in the prologue to one of his comedies printed in that year, speaks of the poet's third day. The unfortunate Otway had no more than one benefit on the production of a new play; and this, too, it seems, he was sometimes forced to mortgage before the piece was acted. Southerne was the first dramatic writer who obtained the emoluments arising from two representations; and to Farquhar, in the year 1700, the benefit of a third was granted. When an author sold his piece to the sharers or proprietors of a theatre, it remained for several years unpublished; but when that was not the case, he printed it for sale, to which many seem to have been induced, from an apprehension that an imperfect copy might be issued from the press without their consent. The customary price of the copy of a play in the time of Shakspeare appears to have been twenty nobles, or six pounds thirteen shillings and fourpence. The play when printed was sold for sixpence; and the usual present from a patron in return for a dedication was forty shillings. On the first day of exhibiting a new play, the prices of admission appear to have been raised; and this seems to have been occasionally practised on the benefit-nights of authors to the end of the last century. The custom of passing a final censure on plays at their first exhibition is as ancient as the time of our author, for no less than three plays of his rival Ben Jonson appear to have been damned; and Fletcher's Faithful Shepherdess, and the Knights of the Burning Pestle, written by him and Beaumont, underwent the same fate.

"It is not easy to ascertain what were the emoluments of a successful actor in the time of Shakspeare. They had not then annual benefits, as at present. The performers at each theatre seem to have shared the profits arising either from each day's exhibition, or from the whole season, among them. From Ben Jonson's Poetaster we learn, that one of either the performers or proprietors had seven shares and a half; but of what integral sum is not mentioned. From the prices of admission into our ancient theatres, which have been already mentioned, I imagine the utmost that the shares of the Globe playhouse could have received on any one day was about L.35. So lately as the year 1685, Shadwell received by his third day, on the representation of the Squire of Alsatia, L.130; which, Downes the prompter says, was the greatest receipt that had been ever taken at Drury-Lane playhouse at single prices. It appears from the manuscripts of Lord Stanhope, treasurer of the chambers to King James I. that the customary sum paid to John Heminge and his company for the performance of a play at court was twenty nobles, or six pounds thirteen shillings and fourpence. And Edward Alleyn mentions in his Diary, that he once had so slender an audience in his theatre called the Fortune, that the whole receipts of the house amounted to no more than three pounds and some odd shillings.

"Thus scanty and meagre were the apparatus and accommodations of our ancient theatres, on which those dramas were first exhibited that have since engaged the attention of so many learned men, and delighted so many thousand spectators. Yet even then, we are told by a writer of that age, 'that dramatic poesy was so lively expressed and represented on the public stages and theatres of this city, as Rome in the age of her pomp and glory never saw it better performed; in respect of the action and art, not of the cost and sumptuousness.'"

PLEA, in *Law*, is what either party alleges for himself in court, in a cause there depending; and in a more restricted sense, it is the defendant's answer to the plaintiff's declaration.

Pleas are usually divided into those of the crown and common pleas. Pleas of the crown are all suits in the king's name, or in the name of the attorney-general in behalf of the king, for offences committed against his crown and dignity, and against his peace; as treason, murder, felony, &c.

Common pleas are such suits as are carried on between common persons in civil cases. These pleas are of two sorts; dilatory pleas, and pleas to the action. Dilatory pleas are such as tend merely to delay or put off the suit, by questioning the propriety of the remedy rather than by denying the injury; pleas to the action are such as dispute the very cause of suit.

PLEASURE is a word so universally understood that it needs no explanation. Lexicographers, however, who must attempt to explain every word, call it "the gratification of the mind or senses." It is directly opposed to *pain*, and constitutes the whole of positive happiness, as that does of misery.

The Author of Nature has furnished us with many pleasures, as well as made us liable to many pains; and we are susceptible of both in some degree as soon as we have life and are endowed with the faculty of sensation. A French writer, in a work[1] which once raised high expectations, contends that a child in the womb of its mother feels neither pleasure nor pain. "These sensations," says he, "are not innate; they have their origin from without; and it is at the moment of our birth that the soul receives the first impressions; impressions slight and superficial at the beginning, but which by time and repeated acts leave deeper traces in the sensorium, and become more extensive and more lasting. It is when the child sends forth its first cries that sensibility or the faculty of sensation is produced, which in a short time gathers strength and stability by the impression of exterior objects. Pleasure and pain not being innate, and being only acquired in the same manner as the qualities which we derive from instruction, education, and society, it follows that we learn to suffer and enjoy as we learn any other science."

This is strange reasoning and strange language. That sensations are not innate is universally acknowledged; but it does not therefore follow that the soul receives its first impressions and first sensations at the moment of birth. The child has life, the power of locomotion, and the sense of touch, long before it is born; and every mother will tell this philosopher that an infant unborn exhibits symptoms both of pain and of pleasure. That many of our organs of sense are improved by use is incontrovertible; but it is so far from being true that our sensible pleasures become more exquisite by being often repeated, that the contrary is experienced in far the greater part of them; and though external objects, by making repeated impressions on the senses, certainly leave deeper traces on the memory than an object once perceived can do, it by no means follows that these impressions become the more delightful the more familiar that they are to us. That we learn to suffer and enjoy as we learn any other science, is a most extravagant paradox; for it is self-evident that we cannot live without being capable in some degree both of suffering and enjoyment, though a man may certainly live to old age in profound ignorance of all the sciences.

The same writer assures us, indeed, that sensation is not necessary to human life. "Philosophers," says he, "make mention of a man who had lost every kind of feeling in every member of his body; he was pinched or pricked to no purpose. Meanwhile this man made use of all his members; he walked without pain, he drank, ate, and slept, without perceiving that he did so. Sensible neither to pleasure nor pain, he was a true natural machine."

To the tale of these anonymous philosophers the author before us gives implicit credit, whilst at the same instant he favours us with the following argumentation, which completely proves its falsehood. "It is true that sensation is a relative quality, susceptible of increase and diminution; that it is not necessary to existence, and that one might live without it; but in this case he would live as an automaton, without feeling pleasure or pain; and he would possess neither idea, nor reflection, nor desire, nor passion, nor will, nor sentiment; his existence would be merely passive, he would live without knowing it, and die without apprehension."

But if this man of the philosophers, whom our author calls an automaton, and a true natural machine, had neither idea, nor desire, nor passion, nor will, nor sentiment (and without sensation he certainly could have none of them), what induced him to walk, eat, or drink, or to cease from any of these operations after they were accidentally begun? The instances of the automata which played on the flute and at chess are not to the purpose for which they are produced; for there is no parallel between them and this natural machine, unless the philosophers wound up their man to eat, drink, walk, or sit, as Vacanson and Kempeler wound up their automata to play or cease from playing on the German flute and at chess.

The author having for a while sported with these harmless paradoxes, proceeds to put the credulity of his reader to the test in regard to others of a very contrary tendency. He institutes an inquiry concerning the superiority, in number and degree, of the pleasures enjoyed by the different orders of men in society; and labours, not indeed by argument, but by loose declamation, to propagate the belief that happiness is very unequally distributed. The pleasures of the rich, he says, must be more numerous and exquisite than those of the poor; the nobleman must have more enjoyments than the plebeian of equal wealth; and the king, according to him, must be the happiest of all men. He owns, indeed, that although birth, rank, honours, and dignity add to happiness, a man is not to be considered as miserable because he is born in the lower conditions of life. A man may be happy as a mechanic, a merchant, or a labourer, provided he enters into the spirit of his profession, and has not imbibed, by a misplaced education, those sentiments which make his condition insupportable. Happiness is of easy acquisition in the middling stations of life; and though perhaps we are unable to know or to estimate exactly the pleasure which arises from contentment and mediocrity, yet happiness being a kind of aggregate of delights, of riches, and of advantages more or less great, every person must have a share of it; the division is not exactly made, but, all other things being equal, there will be more in the elevated than in the inferior conditions of society; the enjoyment will be more felt, the means of enjoying more multiplied, and the pleasures more varied. Birth, rank, fortune, talents, wit, genius, and virtue, are then the great sources of happiness; those advantages are so considerable, that we see men contented with any one of them; but their union forms supreme felicity.

"There is so vast a difference, says Voltaire, between a man who has made his fortune and one who has to make it, that they are scarcely to be considered as creatures of the same kind. The same thing may be said of birth, the greatest of all advantages in a large society; of rank, of honours, and of great abilities. How great a difference is made between a person of high birth and a tradesman; between a Newton or Descartes and a simple mathematician! Ten thousand soldiers are killed on the field of battle, and it is scarcely mentioned; but if the general fall, and especially if he be a man of courage and abilities, the court and city are filled with the news of his death, and the mourning is universal.

---

[1] *Encyclopédie Méthodique*, articles *Logique*, *Métaphysique*, *et Morale*, tom. iv.

"Frederick the Great, king of Prussia, felt in a more lively manner than perhaps any other man the value of great talents. I would willingly renounce, said he to Voltaire, every thing which is an object of desire and ambition to man; but I am certain if I were not a prince I should be nothing. Your merit alone would gain you the esteem, and envy, and admiration of the world; but to secure respect for me, titles, and armies, and revenues, are absolutely necessary."

For what purpose this account of human happiness was published, it is not for us to say. Its obvious tendency, however, is to make the lower orders of society discontented with their state, and envious of their superiors; and it is not unreasonable to suppose, that it contributed in some degree to excite the ignorant part of the author's countrymen to the commission of those atrocities of which they have since been guilty. That such was his intention, the following extract will not permit us to believe; for though in it the author attempts to support the same false theory of human happiness, he mentions virtuous kings with the respect becoming a loyal subject of the unfortunate Louis, whose character he seems to have intentionally drawn, and whose death by the authority of a savage faction he has in effect foretold.

"Happiness, in a state of society, takes the most variable forms; it is a Proteus susceptible of every kind of metamorphosis; it is different in different men, in different ages, and in different conditions. The pleasures of youth are very different from those of old age; what affords enjoyment to a mechanic, would be supreme misery to a nobleman; and the amusements of the country would appear insipid in the capital. Is there, then, nothing fixed with regard to happiness? Is it of all things the most variable and the most arbitrary? Or, in judging of it, is it impossible to find a standard by which we can determine the limits of the greatest good to which man can arrive in the present state? It is evident that men form the same ideas of the beautiful and sublime in nature, and of right and wrong in morality, provided they have arrived at that degree of improvement and civilization of which human nature is susceptible; and that different opinions on these subjects depend on different degrees of culture, of education, and of improvement. The same thing may be advanced with regard to happiness: all men, if equal with respect to their organs, would form the very same ideas on this subject if they reached the degree of improvement of which we are presently speaking; and, in fact, do we not see in the great circles at Rome, at Vienna, at London, and at Paris, that those who are called people of fashion, who have received the same education, have nearly the same taste, the same desires, and the same spirit for enjoyment? There is doubtless a certain degree of happiness to be enjoyed in every condition of life; but as there are some conditions preferable to others, so are there degrees of happiness greater and less; and if we were to form an idea of the greatest possible in the present state, it perhaps would be that of a sovereign, master of a great empire, enjoying good health and a moderate spirit; endowed with piety and virtue; whose whole life was employed in acts of justice and mercy, and who governed by fixed and immoveable laws. Such a king is the image of the Divinity on earth, and he must be the idol of a wise people. His whole life should present a picture of the most august felicity. Although such sovereigns are rare, yet we are not without examples of them. Ancient history affords us Titus and Marcus Aurelius, and the present age can boast of piety and munificence in the character of some of its kings. This state of the greatest happiness to which man can reach not being ideal, it will serve as a standard of comparison by which happiness and misery can be estimated in all civilized countries. *He is as happy as a king*, is a proverbial expression, because we believe with justice that royalty is the extreme limit of the greatest enjoyments; and, in fact, happiness being the work of man, that condition which comprehends all the degrees of power and of glory, which is the source of honour and of dignity, and which supposes in the person invested with it all means of enjoyment either for himself or others, leaves nothing on this earth to which any reasonable man would give the preference.

"We can find also in this high rank the extreme of the greatest evils to which the condition of nature is exposed. A king condemned to death and perishing on a scaffold, by the authority of a faction, while at the same time he had endeavoured, by every means in his power, to promote the general happiness of his subjects, is the most terrible and striking example of human misery; for if it be true that a crown is the greatest of all blessings, then the loss of it, and at the same time the loss of life by an ignominious and unjust sentence, are of all calamities the most dreadful.

"It is also in the courts of kings that we find the most amiable and perfect characters; and it is there where true grandeur, true politeness, the best tone of manners, the most amiable graces, and the most eminent virtues, are completely established. It is in courts that men seem to have acquired their greatest improvement. Whosoever has seen a court, says La Bruyère, has seen the world in the most beautiful, the most enchanting, and attractive colours. The prejudices of mankind in behalf of the great are so excessive, that if they inclined to be good they would be almost the objects of adoration."

In this passage there are doubtless many just observations. But there is at least an equal number of others both false and dangerous. That a crown is the greatest of all earthly blessings, and that it is in the courts of kings that we meet with the most amiable and perfect characters, are positions which a true philosopher will not admit, except with great limitations. The falsehood of the author's general theory respecting the unequal distribution of happiness in society, we need not waste time in exposing. It is sufficiently refuted in other articles of this work. (See MORAL PHILOSOPHY.) He enters upon other speculations respecting the pleasures and pains of savages, which are ingenious, and worthy of attention; but before we proceed to notice them, it will be proper to consider the connection which subsists between pleasure and pain.

"That the cessation of pain is accompanied by pleasure, is a fact, "says Dr Sayers," which has been repeatedly observed, but perhaps not sufficiently accounted for. Let us suppose a person in a state of indifference as to heat. Upon coming near a fire, he will experience at first an agreeable warmth, that is, pleasure. If the heat be increased, this state of pleasure will, after a time, be converted into one of pain, from the increased action upon the nerves and brain, the undoubted organs of all bodily sensations. Let the heat now be gradually withdrawn; the nervous system must acquire again, during this removal, the state of agreeable warmth or pleasure; and after passing through that state it will arrive at indifference. From this fact then we may conclude that a state of pleasure may be pushed on till it is converted into one of pain; and, on the other hand, that an action which produces pain will, if it go off gradually, induce at a certain period of its decrease a state of pleasure. The same reasoning which has thus been applied to the body may be extended also to the mind. Total languor of mind is not so pleasant as a certain degree of action or emotion; and emotions pleasant at one period may be increased till they become painful at another; whilst painful emotions, as they gradually expire, will, at a certain period of their decrease, induce a state of pleasure. Hence then we are able to explain why pleasure should arise in all cases from the gradual cessation of any action or emotion which produces pain."

The same author maintains, that from the mere removal of pain, whether by degrees or instantaneously, we always experience pleasure; and if the pain removed was exquisite, what he maintains is certainly true. To account for this phenomenon he lays down the following law of nature, which experience abundantly confirms, viz. "that the temporary withdrawing of any action from the body or mind invariably renders them more susceptible of that action when again produced." Thus, after long fasting, the body is more susceptible of the effects of food than if the stomach had been lately satisfied; the action of strong liquors is found to be greater on those who use them seldom than on such as are in the habit of drinking them. Thus, too, with respect to the mind; if a person be deprived for a time of his friend's society, or of a favourite amusement, the next visit of his friend, or the next renewal of his amusement, is attended with much more pleasure than if they had never been withheld from him.

"To apply this law to the case of a person suddenly relieved from acute pain. While he labours with such pain, his mind is so totally occupied by it, that he is unable to attend to his customary pursuits or amusements. He becomes therefore so much more susceptible of their action, that when they are again presented to him, he is raised above his usual indifference to positive pleasure. But all pains do not proceed from an excess of action. Many of them arise from reducing the body or the mind to a state below indifference. Thus, if a person have just sufficient warmth in his body to keep him barely at ease or in a state of indifference, by withdrawing this heat, a state of uneasiness or pain is produced; and if in a calm state of mind one be made acquainted with a melancholy event, his quiet is interrupted, and he sinks below indifference, into a painful state of mind. If, now, without communicating any new source of pleasure, we remove in the former case the cold, and in the latter the grief, the persons from whom they are removed will experience real pleasure. Thus, then, whether pain arises from excess or deficiency of action, the gradual or the sudden removal of it must be in all cases attended with pleasure."[1] It is equally true that the gradual or sudden removal of pleasure is attended with pain.

We are now prepared to examine the French author's account of the pleasures and pains of savages. "Every age," says he, "has its different pleasures; but if we were to imagine that those of childhood are equal to those of confirmed age, we should be much mistaken in our estimation of happiness. The pleasures of philosophy, either natural or moral, are not unfolded to the infant; the most perfect music is a vain noise; the most exquisite perfumes and dishes highly seasoned offend his young organs instead of affording delight; his touch is imperfect; forty days elapse before the child gives any sign of laughter or of weeping; his cries and groans before that period are not accompanied with tears; his countenance expresses no passion; the parts of his face bear no relation to the sentiments of the soul, and are moreover without consistency. Children are but little affected with cold; whether it be that they feel less, or that the interior heat is greater than in adults. In them all the impressions of pleasure and pain are transitory; their memory has scarcely begun to unfold its powers; they enjoy nothing but the present moment; they weep, laugh, and give tones of satisfaction without consciousness, or at least without reflection; their joy is confined to the indulgence of their little whims, and constraint is the greatest of their misfortunes; few things amuse, and nothing satisfies them. In this happy condition of early infancy nature is at the whole expense of happiness; and the only point is not to contradict her. What desires have children? Give them liberty in all their movements, and they have a plenitude of existence, an abundance of that kind of happiness which is confined in some sort to all the objects which surround them; but if all beings were happy on the same conditions, society would be at no expense in procuring the happiness of the different individuals who compose it. Sensation is the foundation of reflection; it is the principal attribute of the soul; it is by this that man is elevated to sublime speculations, and secures his dominion over nature and himself. This quality is not stationary, but susceptible, like all other relative qualities, of increase and decay, of different degrees of strength and intenseness: it is different in different men; and in the same man it increases from infancy to youth, from youth to confirmed manhood: at this period it stops, and gradually declines as we proceed to old age and to second childishness. Considered physically, it varies according to age, constitution, climate, and food; considered in a moral point of view, it takes its different appearances from individual education, and from the habits of society; for man in a state of nature and society, with regard to sensation and the unfolding of his powers, may be considered as two distinct beings; and if one were to make a calculation of pleasure in the course of human life, a man of fortune and capacity enjoys more than ten thousand savages.

"Pleasure and pain being relative qualities, they may be almost annihilated in the moment of vehement passion. In the heat of battle, for example, ardent and animated spirits have not felt the pain of their wounds; and minds strongly penetrated with sentiments of religion, enthusiasm, and humanity, have supported the most cruel torments with courage and fortitude. The sensibility of some persons is so exquisitely alive, that one can scarcely approach them without throwing them into convulsions. Many diseases show the effect of sensibility pushed to an extreme; such as hysteric affections, certain kinds of madness, and some of those which proceed from poison, and from the bite or sting of certain animals, as the viper and the tarantula. Excessive joy or grief, fear and terror, have been known to destroy all sensation, and occasion death."[2]

Having made these preliminary observations on pleasure and pain in infancy, and as they are increased or diminished by education, and the different conditions of body and mind, the same author proceeds to consider the capability of savages to feel pleasure and pain. "By savages he understands all the tribes of men who live by hunting and fishing, and on those things which the earth yields without cultivation. Those tribes who possess herds of cattle, and who derive their subsistence from such possessions, are not to be considered as savages, as they have some idea of property. Some savages are naturally compassionate and humane, others are cruel and sanguinary. Although the physical constitution of man be everywhere the same, yet the varieties of climate, the abundance or scarcity of natural productions, have a powerful influence to determine the inclinations; even the fierceness of the tiger is softened under a mild sky. Now nature forms the manners of savages just as society and civil institutions form the manners of civilized life. In the one case climate and food produce almost the whole effect; in the other they have scarcely any influence. The habits of society every moment contend with nature, and they are almost always victorious. The savage devotes himself to the dominion of his passions; the civilized man is employed in restraining, in directing, and in modifying them: so much influence have government, laws, society, and the fear of censure and punishment, over his soul.

[1] Disquisitions Metaphysical and Literary.

[2] There are instances of persons who have died in consequence of the noise of thunder, without being touched. A man frightened by the fall of a gallery in which he happened to be, was immediately seized with the black jaundice. M. le Cat mentions a young person on whom the insolence of another made such an impression, that his countenance became at first yellow, and then changed into black, in such a manner that in less than eight days he appeared to wear a mask of black velvet; and he continued in this state for four months, without any other symptom of bad health, or any pain. A sailor was so terrified in a storm, that his face sweated blood, which, like ordinary sweat, returned as it was wiped off. Stahl, whose testimony cannot be called in question, cites a similar case of a girl who had been frightened by soldiers. The excess of fear, according to many physicians, produces madness and epilepsy.

" It is not to be doubted that savages are susceptible both of pleasure and pain; but are the impressions made on their organs as sensible, or do they feel pain in the same degree with the inhabitants of a civilized country?

" Their enjoyments are so limited, that if we confine ourselves to truth, a few lines will be sufficient to describe them: our attention must therefore be confined to pain, because the manner in which they support misfortune, and even torture, presents us with a view of character unequalled in the history of civilized nations. It is not uncommon in civilized countries to see men braving death, meeting it with cheerfulness, and even not uttering complaints under the torture; but they do not insult the executioners of public vengeance, and defy pain in order to augment their torments; and those who are condemned by the laws suffer the punishment with different degrees of fortitude. On those mournful occasions, the common ranks of mankind in general die with less firmness: those, on the other hand, who have received education, and who by a train of unfortunate events are brought to the scaffold, whether it be the fear of being reproached with cowardice, or the consideration that the stroke is inevitable, such men discover the expiring sighs of self-love even in their last moments; and those, especially of high rank, from their manners and sentiments, are expected to meet death with magnanimity: but an American savage in the moment of punishment appears to be more than human; he is a hero of the first order, who braves his tormentors, who provokes them to employ all their art, and who considers it his chief glory to bear the greatest degree of pain without shrinking. The recital of their tortures would appear exaggerated, if it were not attested by the best authority, and if the savage nations among whom those customs are established were not sufficiently known; but the excess of the cruelty is not so astonishing as the courage of the victim. The European exposed to sufferings of the same dreadful nature would rend heaven and earth with his piercing cries and horrible groans; the reward of martyrdom, the prospect of eternal life, could alone give him fortitude to endure such torments; but the savage is not animated with this exalted hope. What supports him, then, in scenes of so exquisite suffering? The feeling of shame, the fear of bringing reproach on his tribe, and giving a stain to his fellows never to be wiped away, are the only sentiments which influence the mind of a savage, and which, always present to his imagination, animate him, support him, and lend him spirit and resolution. At the same time, however powerful those motives may be, they would not be alone sufficient, if the savage felt pain in the same degree with the European. Sensibility, as we have already observed, is increased by education; it is influenced by society, manners, laws, and government; climate and food work it into a hundred different shapes; and all the physical and moral causes contribute to increase and diminish it. The habitual existence of a savage would be a state of suffering to an inhabitant of Europe. You must cut the flesh of the one, and tear it away with your nails, before you can make him feel in an equal degree to a scratch or prick of a needle in the other. The savage, doubtless, suffers under torture, but he suffers much less than an European in the same circumstances: the reason is obvious; the air which the savages breathe is loaded with fog and moist vapours; their rivers not being confined by high banks, are by the winds as well as in floods spread over the level fields, and deposit on them a putrid and pernicious slime; the trees, squeezed one upon another in that rude and uncultivated country, serve rather as a covering to the earth than an ornament. Instead of those fresh and delicious shades, those openings in the woods, and walks crossing each other in all directions, which delight the traveller in the fine forests of France and Germany; those in America serve only to intercept the rays of the sun, and to prevent the benign influence of his beams. The savage participates of this cold humidity; his blood has little heat, his humours are gross, and his constitution phlegmatic. To the powerful influence of climate it is necessary to join the habit of his life. Obliged to traverse vast deserts for subsistence, his body is accustomed to fatigue; food not nourishing, and at the same time in no great plenty, blunts his feelings; and all the hardships of the savage state give a rigidity to his members which makes him almost incapable of suffering. The savage in this state of nature may be compared to our water-women and street-porters, who, though they possess neither great vigour nor strength, are capable of performing daily, and without complaint, that kind of labour which to a man in a different condition of life would be a painful and grievous burden. Feeling, in less perfection with the savage, by the effects of climate and food, and the habits of his life, is still farther restrained by moral considerations. The European is less a man of nature than of society: moral restraints are powerful with him, whilst over the American they have scarcely any influence. This latter, then, is in a double condition of imperfection with regard to us; his senses are blunted, and his moral powers are not disclosed. Now, pleasure and pain depending on the perfection of the senses and the unfolding of the intellectual faculties, it cannot be doubted, that in enjoyments of any kind savages experience less pleasure, and in their suffering less pain, than Europeans in the same circumstances. And, in fact, the savages of America possess a very feeble constitution. They are agile without being strong; and this agility depends more on their habits than on the perfection of their members: they owe it to the necessity of hunting; and they are moreover so weak, that they were unable to bear the toil which their first oppressors imposed on them. Hence a race of men in all respects so imperfect could not endure torment under which the most robust European would sink, if the pain which they feel were really as great as it appears to be. Feeling is, then, and must necessarily be, less in the savage condition; for this faculty disclosing itself by the exercise of all the physical and moral qualities, must be less as they are less exercised. Everything shows the imperfection of this precious quality, this source of all our affections, in the American savages.

" All the improvements in Europe have had a tendency to unfold sensibility; the air is purified that we may breathe more freely; the morasses are drained, the rivers are regulated in their courses, the food is nourishing, and the houses commodious. With the savages, on the contrary, everything tends to curb it; they take pleasure even in hardening the organs of the body, in accustoming themselves to bear by degrees the most acute pain without complaining. Boys and girls among the savages amuse themselves with tying their naked arms together, and laying a kindled coal between them, to try which of them can longest suffer the heat; and the warriors who aspire to the honour of being chief, undergo a course of suffering which exceeds the idea of torture inflicted on the greatest criminals in Europe."

These observations on the pleasures and pains of savages appear to be well founded, and, as the attentive reader will perceive, are perfectly agreeable to the theory of Dr Sayers. If, indeed, that theory be just, as we believe it to be, it will follow, that the few pleasures of sense which the American enjoys, he ought to enjoy more completely than any European, because to him they recur but seldom. This may very possibly be the case, and certainly would be so, were not his fibres, by climate and the habits of his life, rendered more rigid than those of the civilized part of the inhabitants of Europe. But if we agree with this author[1] in what he says of the pains and pleasures of savages, we cannot admit, without many exceptions, his theory of the enjoyments of children. It is so far from being true that few things amuse, and that nothing satisfies them, that the direct contrary must have been observed by every man attentive to the operations of the infant mind, which is amused with everything new, and often completely satisfied with the merest trifle. The pleasures of philosophy are not indeed unfolded to the infant; but it by no means follows that he does not enjoy his rattle and his drum as much as the philosopher enjoys his telescope and his air-pump; and if there be any truth in the science of physiognomy, the happiness of the former is much more pure and exquisite than that of the latter. That the most perfect music is vain noise to an infant, is far from being self-evident, unless the author confines the state of infancy to a very few months; and we are not disposed to believe, without better evidence than we have yet received, that the relish of exquisite perfumes and highly-seasoned dishes adds much to the sum of human felicity.

But however much we disapprove of many of these reflections, the following we cordially approve and adopt. "If we compare," says our author, "the pleasures of sense with those which are purely intellectual, we shall find that the latter are infinitely superior to the former, as they may be enjoyed at all times and in every situation of life. What are the pleasures of the table, says Cicero, of gaming, and of women, compared with the delight of study? This taste increases with age, and no happiness is equal to it. Without knowledge and study, says Cato, life is almost the image of death.[2] The pleasures of the soul are such, that it is frequent enough to see men preserve their gaiety during their whole life, notwithstanding a weak, diseased, and debilitated body. Scaron, who lived in the last century, was an example of this. Balzac, speaking of him, says that Prometheus, Hercules, and Philoctetes, in profane, and Job in sacred history, said many great things while they were afflicted with violent pain; but Scaron alone said pleasant things. I have seen, continues he, in many places of ancient history, constancy, and modesty, and wisdom, and eloquence, accompanying affliction; but he is the only instance wherein I have seen pleasantry.

"There are men whose understandings are constantly on the stretch, and by this very means they are improved; but if the body were as constantly employed in the pursuit of sensual gratification, the constitution would soon be destroyed. The more we employ the mind we are capable of the greater exertion; but the more we employ the body we require the greater repose. There are, besides, but some parts of the body capable of enjoying pleasure; every part of it can experience pain. A toothach occasions more suffering than the most considerable of our pleasures can procure of enjoyment. Great pain may continue for any length of time; excessive pleasures are almost momentary. Pleasure carried to an extreme becomes painful; but pain, either by augmenting or diminishing it, never becomes agreeable. For the moment, the pleasures of the senses are perhaps more satisfactory; but in point of duration, those of the heart and mind are infinitely preferable. All the sentiments of tenderness, of friendship, of gratitude, and of generosity, are sources of enjoyment for man in a state of civilization. The damned are exceedingly unhappy, said St Catherine de Sienna, if they are incapable of loving or being beloved.

"Pleasure, continued for a great length of time, produces languor and fatigue, and excites sleep; the continuation of pain is productive of none of these effects. Many suffer pain for eight days, and even a month, without interruption; an equal duration of excessive pleasure would occasion death.

"Time is a mere relative idea with regard to pleasure and pain; it appears long when we suffer, and short when we enjoy. If there existed no regular and uniform movement in nature, we would not be able from our sensations alone to measure time with any degree of exactness, for pain lengthens and pleasure abridges it. From the languor of unoccupied time has arisen the proverb expressive of our desire to kill it. It is a melancholy reflection, and at the same time true, that there is no enjoyment which can effectually secure us from pain for the remainder of our lives; while there are examples of evils which hold men in constant sorrow and pain during their whole existence. Such, then, is the imperfection of the one and the power of the other.

"Pleasure and pain are the sources of morality; an action is just or unjust, good or otherwise, only as its natural tendency is to produce suffering or enjoyment to mankind. No crime could be committed against a being altogether insensible, nor could any good be bestowed on it. Unless he were endowed with the desire of pleasure and the apprehension of pain, man, like an automaton, would act from necessity, without choice and without determination.

"All our passions are the development of sensibility. If we were not possessed of feeling, we should be destitute of passions; and as sensibility is augmented by civilization, the passions are multiplied; more active and vigorous in an extensive and civilized empire than in a small state; more in the latter than among barbarous nations; and more in these last than among savages. (See PASSION.) There are more passions in France and England than in all the nations of Europe; because everything which serves to excite and foster them is always in those countries in the greatest state of fermentation. The mind is active; the ideas great, extensive, and multiplied. And is it not the soul, the mind, and heart, which are the focus of all the passions?"

But wherever the passions are multiplied, the sources of pleasure and pain are multiplied along with them. This being the case, it is impossible to prescribe a fixed and general rule of happiness suited to every individual. There are objects of pleasure with regard to which all men of a certain education are agreed; but there are perhaps many more, owing to the variety of tempers and education, about which they differ. Every man forms ideas of enjoyment relative to his character; and what pleases one may be utterly detested by another. In proportion as a nation is civilized and extensive, those differences are remarkable. Savages, who are not acquainted with all the variety of European pleasures, amuse themselves with very few objects. Owing to the want of civilization, they have scarcely any choice in the objects of taste. They have few passions; we have many. But even in the nations of Europe, pleasure is infinitely varied in its modification and forms. Those differences arise from manners, from governments, from political and religious customs, and chiefly from education. Meanwhile, however different and variable the ideas of pleasure may be amongst nations and individuals, it still remains a fact, that a certain number of persons in all civilized states, whether distinguished by birth, or rank, or fortune, or talents, as they have nearly the same education, so they form nearly the same ideas of happiness; but, to possess it, a man must give his chief application to the state of his mind; and, notwithstanding all his efforts, it is of uncertain duration. Happiness is the sunshine of life; we enjoy it frequently at great intervals, and it is therefore necessary to know how to use it. All the productions of art perish; the largest fortunes are dissipated; rank, honour, and dignity, pass away like a shadow; the memory is impaired; all the faculties of the soul are extinguished; the body sinks under the infirmities of old age; and scarcely has one reached the boundaries of happiness marked out by his imagination, when he must give place to another, and renounce all his pleasures, all his hopes, all his illusions, the fugitive images of which had given happiness to the mind.

---

[1] *Encyclopédie Méthodique*, articles *Logique*, *Métaphysique*, *et Morale*, tom. iv.

[2] "Savages, barbarians, and peasants, enjoy little happiness except that of sensation. The happiness of a civilized and well-informed man consists of sensations, of ideas, and of a great number of affinities, altogether unknown to them. He not only enjoys the present, but the past and the future. He recalls the agreeable idea of pleasures which he has tasted. It is great happiness, says an ancient, to have the recollection of good actions, of an upright intention, and of promises which we have kept."

There are pleasures, however, on which the mind may securely rest, and which elevate man above himself, dignify his nature, fix his attention on spiritual things, and render him worthy of the care of Providence. These are to be found in true religion, which procures for those who practise its duties, inexpressible happiness in a better country, and is in this world the support of the weak and the consolation of the unfortunate.

PLEBEIAN, any person of the rank of the common people. It is chiefly used in speaking of the ancient Romans, who were divided into senators, patricians, and plebeians. The distinction was made by Romulus, the founder of the city, who confined all dignities, civil, military, and sacerdotal, to the rank of patricians. But, to prevent the seditions which such a distinction might produce, through the pride of the higher order and the envy of the lower, he endeavoured to engage them one to another by reciprocal ties and obligations. Every plebeian was allowed to choose, out of the body of the patricians, a protector, who should be obliged to assist him with his interest and substance, and to defend him from oppression. These protectors were called patrons; the protected, clients. It was the duty of the patron to draw up the contracts of the clients, to extricate them out of their difficulties and perplexities, and to guard their ignorance against the artfulness of the crafty. On the other hand, if the patron was poor, his clients were obliged to contribute to the portions of his daughters, the payment of his debts, and the ransom of him and his children if they happened to be taken in war. The client and patron could neither accuse nor bear witness against each other; and if either of them was convicted of having violated this law, the crime was equal to that of treason, and any one might with impunity slay the offender as a victim devoted to Pluto and the infernal gods. For more than six hundred years we find no dissensions or jealousies between the patrons and their clients; not even in the times of the republic, when the people frequently mutinied against the great and powerful.

PLECTRUM, Greek, πλῆκτρον, a small implement of wood, horn, ivory, metal, &c. employed to strike the strings of certain musical instruments used among the ancient Egyptians, Greeks, and Arabians. It was of various shapes, often consisting of a heart-shaped head, and a short handle. In some of the ancient Egyptian paintings at Thebes, are representations of a three-stringed guitar, with an oval body and long neck, having a plectrum attached by a string to the neck, close to its junction with the body. Several foreign stringed instruments are still played with a plectrum, and amongst them the *Tamboora* of Hindustan.

PLEDGE (*plegius*), in common law, a surety or gage, either real or personal, which the plaintiff or demandant is to find for his prosecuting the suit.

To PLEDGE, in drinking, denotes to warrant, or to be surety to one, that he shall receive no harm whilst he is taking his draught. The phrase is referred by antiquaries to the practice of the Danes heretofore in England, who used frequently to stab or cut the throats of the natives whilst they were drinking.

PLEDGERY, or PLEGGERY, in *Law*, suretiship, or an undertaking or answering for another.

PLEIADES, in fabulous history, the seven daughters of Atlas king of Mauritania, and Pleione, who were so called from their mother. They were Maia, Electra, Taygete, Asterope, Merope, Halcyone, and Celœno, who were also called *Atlantides*, from their father Atlas. These princesses were carried off by Busiris king of Egypt; but Hercules, having conquered him, delivered them to their father. Yet they afterwards suffered a new persecution from Orion, who pursued them five years, until Jupiter, being prevailed on by their prayers, took them up into the heavens, where they form the constellation which bears their name.

PLEIADES, in *Astronomy*, an assemblage of seven stars, in the neck of the constellation Taurus.

These stars are so called from the Greek πλειν, *navigare*, to sail; as being terrible to mariners, by reason of the rains and storms which frequently rise with them. The Latins called them *vergiliæ*, from *ver*, spring; because of their rising about the time of the vernal equinox. The largest is of the third magnitude, and is called *lucida Pleiadum*.

PLENARY, something complete or full. Thus we say the pope grants *plenary* indulgences, that is, full and entire remissions of the penalties due to all sins.

PLENIPOTENTIARY, a person vested with full power to do any thing.

PLENITUDE, the quality of a thing that is full, or that fills another. In medicine, it chiefly denotes a redundancy of blood and humours.

PLENUM, in *Physics*, denotes, according to the Cartesians, that state of things in which every part of space is supposed to be full of matter, in opposition to a *vacuum*, which is a space supposed to be devoid of all matter.

PLEONASM, a figure in *Rhetoric*, by which we may use words seemingly superfluous, to express a thought with the greater energy; such as, "I saw it with my own eyes," "I heard it with my own ears," and the like.

PLETHORA, in *Medicine*, from πληθος, *plenitude*. A plethora is, when the vessels are too much loaded with fluids. The plethora may be sanguine or serous. In the former there is too much *crassamentum* in the blood, in the latter too little. In the sanguine plethora, there is danger of a fever, inflammation, apoplexy, rupture of the blood-vessels, and obstructed secretions; in the serous, of a dropsy, and other affections. A rarefaction of the blood produces all the effects of a plethora; it may accompany a plethora, and should therefore be distinguished from it. Mr Bromfield observes, that a sanguine plethora may be known to be present by the pulse. An artery overcharged with blood is as incapable of producing a strong full pulse, as one that contains a deficient quantity; so that in both cases there will be a low and weak pulse. To distinguish rightly, the pulse must not be felt with one or two fingers on the carpal artery; but if three or four fingers cover a considerable length of the artery, and we press hard for some time on it, and then suddenly raise all these fingers except that which is nearest to the patient's hand, the influx of the blood, if there is a plethora, will be so rapid as to raise the other finger, and make us sensible of the fulness. The sanguine plethora is relieved by bleeding; the serous by purging, diuretics, and sweating.

PLEXUS, amongst anatomists, a bundle of small vessels interwoven in the form of network. Thus a congeries of vessels within the brain is called *plexus choroides, reticularis*, or *retiformis*. A plexus of nerves is the union of two or more nerves forming a sort of ganglion or knot.

PLICA POLONICA, or *Plaited Hair*, is a disease peculiar to Poland, and hence the name. Mr Coxe, who gives a short account of it, attempts likewise to assign the physical causes which are supposed to produce it. Many causes of this kind, he tells us, have been supposed to concur in rendering the plica more frequent in those regions than in other parts. It would be an endless task to enumerate the various conjectures by which each person has endeavoured to support his favourite hypothesis. The most probable are those assigned by Dr Vicat. The first cause is the nature of the Polish air, which is rendered insalubrious by numerous woods and morasses, and occasionally derives an uncommon keenness, even in the midst of summer, from the position of the Carpathian Mountains; for the south and south-easterly winds, which usually convey warmth in other regions, are in this chilled in their passage over the snowy summits of this range. The second is unwholesome water; for although Poland is not deficient in good springs, yet the common people usually drink that which is nearest at hand, taken indiscriminately from rivers, lakes, and even stagnant pools. The third cause is the gross inattention of the natives to cleanliness. Indeed experience shows, that those who are not negligent in their persons and habitations, are less liable to be afflicted with the plica than others who are deficient in these particulars. Thus persons of the higher ranks are less subject to this disorder than those of inferior stations, the inhabitants of large towns less than those of small villages, the free peasants less than those in an absolute state of vassalage, the natives of Poland Proper less than those of Lithuania. Whatever we may think as to the possibility of all or any of these causes, by themselves, or in conjunction with others, originally producing the disorder, we may venture to assert, that they all, and particularly the last, assist its propagation, inflame its symptoms, and protract its cure. In a word, the plica polonica appears to be a contagious distemper, which, like the leprosy, still prevails amongst a people ignorant in medicine, and inattentive to check its progress, but is rarely known in those countries where proper precautions are taken to prevent its spreading.

PLINIUS SECUNDUS, C., a celebrated Roman writer, but who is to be distinguished from his nephew, Pliny the younger. He was born A. D. 23, in the tenth year of Tiberius, and died on the 2d of November, A. D. 80, the first year of the Emperor Titus, and the day after the eruption of Mount Vesuvius. Two cities contend for the honour of giving birth to him; but the inhabitants of Novum Comum, now *Como*, seem to have a better claim to him as their fellow-citizen than those of Verona. His earlier years were spent under the profligate reign of Caligula and Claudius, but he does not appear to have mingled in the dissolute scenes of those times. Though he devoted himself to the study of literature, he did not withdraw himself from the active business of life. It appears that he served his first military campaign in Africa, probably about his twenty-third year, and that he afterwards spent some time in Germany, under his friend and commander L. Pomponius Secundus, whom we find in Tacitus to have triumphed over the Catti. It was about this time, A. D. 48, that he published his work entitled *De Jaculatione Equestri;* and as Pomponius died shortly after his triumph, Pliny performed the mournful though pleasing duty of transmitting to posterity the transactions of his friend, in a work entitled *Pomponii Vita*. He next devoted himself to forensic duties, and displayed the same activity and zeal in defending the causes of his fellow-citizens, as he had before done in maintaining the honour of his country by arms. It seems probable that at this time he published his work *Studiorum Tres Libri*, divided into six volumes, which was a manual for the formation of an orator, a subject which was subsequently treated by Quintilian. He also published another work, *Germanica Bella*, in which he gave a detailed account of the wars of Drusus and Germanicus. In the reign of Nero, Pliny was employed in Spain as Procurator Cæsaris; an equestrian dignity, but with the duties of which we are by no means well acquainted. He employed his leisure hours in making a selection of passages from various authors, called *Electorum Commentarii*, which on his death he left, to the number of one hundred and sixty, to his nephew. He also published, about A. D. 67, a grammatical work, *Dubii Sermonis Libri Octo;* and thirty-one books of History, which was a continuation of that of Aufidius Bassus, who seems to have written an account of the civil wars. Pliny became the intimate friend of Vespasian and his son Titus; and it was in the reign of the former, A. D. 77, that he published his celebrated work, *Historia Naturalis*, in thirty-seven books. Two years afterwards, Pliny was stationed at Misenum, in Campania, in command of the fleet; and when the eruption of Vesuvius broke out, he hurried towards it, to assist his friends, and to examine more minutely this wonderful phenomenon of nature. But he fell a victim to his thirst for knowledge; being suffocated by the sulphureous exhalations, as he was approaching the mountain from the side of Stabiæ, now *Castellamare*.

The work for which he is most distinguished is his Natural History, the materials for which he has drawn from upwards of two thousand authors, which have generally disappeared. It was divided into thirty-six books, with a dedication to Titus, and a kind of index of the whole; but these are now considered as the first book. The second book contains introductory remarks on astronomy and meteorology; and from the third to the sixth inclusive we have a description of the earth, the lands and their inhabitants, being a sort of universal geography, though it is frequently nothing more than a simple enumeration of names. Then follows the Natural History, beginning with the animal kingdom, which occupies from the seventh to the eleventh books; then botany from the twelfth to the nineteenth. With the twentieth begins his account of the medicinal qualities of various herbs, which extends to the twenty-seventh; and then of the medicines which may be prepared from animals, to the thirty-second. The remaining books are occupied with the mineral kingdom, in which he takes occasion to introduce much curious information respecting the fine arts, sculpture, painting, &c.; and concludes with an account of the most celebrated artists and their works. Cuvier, who was so well able to judge of the value of such a work, thus expresses himself. "Ce grand ouvrage est le seule de Pline qui soit arrivé jusqu'à nous. Il est en même temps l'un des monumens les plus précieux que l'antiquité nous ait laissés, et la preuve d'une érudition bien étonnante dans un homme de guerre et un homme d'état. Pour apprécier avec justice cette vaste et célèbre composition, il est nécessaire d'y distinguer le plan, les faits, et le style. Le plan en est immense. Pline ne se propose point d'écrire seulement une Histoire Naturelle dans le sens restreint où nous prenons aujourd'hui cette science, c'est-à-dire, un traité, plus ou moins détaillé, des animaux, des plantes, et des mineraux; il embrasse l'astronomie, la physique, la géographie, l'agriculture, le commerce, la médecine, et les arts, aussi bien que l'Histoire Naturelle proprement dite; et il mêle sans cesse à ce qu'il en dit des traits relatif, à la connaissance moralé de l'homme, et à l'histoire des peuples, en sorte qu'à beaucoup d'égards on a pu dire de cet ouvrage qu'il était l'Encyclopédie de son temps........Pline n'a point été un observateur tel qu'Aristote; encore moins un homme de génie, capable, comme ce grand philosophe, de saisir les lois et les rapports d'après lesquels la nature a co-ordonné ses productions. Il n'est en général qu'un compilateur, et même le plus souvent un compilateur qui, n'ayant point par lui-même d'idée des choses sur lesquelles il rassemble les témoignages des autres, n'a pu apprécier la vérité de ces témoignages, ni même toujours comprendre ce qu'ils avaient voulu dire.......Si Pline a pour nous aujourd'hui peu de mérite comme critique et comme naturaliste, il n'en est pas de même de son talent comme écrivain, ni du trésor immense de termes et de locutions Latines dont l'abondance des matières l'a obligé de se servir, et qui ont fait de son ouvrage l'un des plus riches dépôts de la langue des Romains. Malgré les défauts que nous sommes obligés de lui reconnaître quand nous le considérons comme naturaliste, nous ne le regardons pas moins comme l'un des auteurs les plus recommandables et les plus dignes d'être placés au nombre des classiques parmi ceux qui ont écrit après le règne d'Auguste."

The best edition of Pliny is that edited by Cuvier, assisted by other learned men in France, and published by Lemaire, Paris, 1827–1832, ten vols.

PLINIUS Cæcilius Secundus, C., a celebrated Roman orator, was the son of L. Cæcilius, and Plinia, the sister of Pliny the elder, and born in the village of Como, in Cisalpine Gaul, though others have considered Verona as the place of his birth. He was born A. D. 62, in the eighth year of the reign of Nero, the same year in which the poet Persius died; and there seems every reason to believe that he died A. D. 107, in the forty-fifth year of his age, and in the tenth year of the reign of Trajan. Having been left fatherless at an early age, he was adopted by his uncle; and, through his care and that of Virginius Rufus, received the best education that Rome could furnish. Amongst others, he derived much advantage from the talents of Quintilian; and he seems at a very early age to have devoted his attention to poetry. In his fourteenth year he had already written a Greek tragedy, though he does not venture to affirm that it was of much value. He had no sooner finished his youthful studies than we find him in Syria, acting as military tribune; and in his eighteenth year, A. D. 80, he was living with his uncle at Misenum, in Campania, where he was commander of the fleet at the moment of the eruption of Vesuvius, which proved fatal to him. Of the calamity, and the phenomena attendant on it, he gives a very affecting and beautiful account, in two letters to the historian Tacitus. On his return to Rome he commenced his career as an orator, and soon became one of the most distinguished ornaments of the Roman bar. He rose gradually through different ranks till he reached the office of prætor; but towards the end of the reign of Domitian, he drew upon himself the indignation of that monarch, by his able defence of Helvidius, whom Domitian had doomed to destruction; and he was only saved from sharing the fate of many others by the death of the emperor. About the period of Nerva's accession (A. D. 96) he lost his wife, the step-daughter of Vectius Proculus, and the following year married Calpurnia, of an illustrious family, with whom he lived very happily, though by neither of his wives had he any children. Trajan raised him, A. D. 100, to the rank of consul suffectus, upon which occasion he delivered that celebrated panegyric on the emperor which has been preserved to us. The second year after his consulship he was appointed by Trajan to the administration of the province of Bithynia; and it was whilst he was in this office that he wrote that letter to the emperor which bears such honourable testimony to the Christian religion, and which induced Trajan to mitigate the laws which bore so heavily on those who professed that faith. On his return from his province he seems only to have survived a few years, which were probably spent in retirement in his magnificent villas, of which he possessed several in different parts of Italy.

He was of the most amiable disposition, kind to his inferiors, generous and hospitable to his friends, amongst whom he numbered Quintilian, Suetonius, Silius Italicus, Martial, and Tacitus. He was the active and zealous patron of learning, dividing his time between his professional employments and the pursuits of literature. He has been accused of being jealous of the reputation of some of his friends; and there is no doubt that he was vain of his own acquirements. Next to Cicero there is certainly no orator so distinguished; yet of his numerous orations not one has been preserved except his Panegyric on Trajan, in which he returns thanks for having raised him to the consulship. It was received with great applause, and is without doubt one of the most beautiful specimens of Roman eloquence that we possess. He exhibits before us Trajan, invested, not merely with the majesty of a prince and commander, but with all the virtues which dignify a private character. His noble spirit, his integrity, his love of learning, are all beautifully pourtrayed; but in his praise he sometimes exceeds the bounds of propriety, so as to give it the appearance of flattery. He has also too great fondness for antithesis, and too constant a repetition of particular expressions. In his language, also, we have sometimes to regret the simplicity which distinguishes the works of an earlier age.

His epistles are addressed to different persons, upon a variety of occasions, and are divided into ten books, of which the last contains only those to Trajan, with his answers. As Sidonius Apollinaris speaks only of nine books, some have thereby been induced to consider the tenth as not the genuine production of Pliny; and indeed others have also refused to include the ninth. The subject-matter of these letters is of a very pleasing character. The reader is interested not more by the variety of circumstances presented to the mind, than by the agreeable manner in which they are told. They possess also great historical value, from being memorials of a period of which we have only a few unimportant hints. We refer more particularly to the two letters on the life and death of Pliny the elder, and that to Trajan on the character of the Christians. As the letters of Cicero are of great value in elucidating the events of the later years of the republic, and in making us more intimately acquainted with the leading statesmen of that time, so those of Pliny are equally valuable in admitting us to an acquaintance with the very different times of the empire.

The best edition is that of Schöfer, with the notes of Gesner and Ernesti, Leipzig, 1805, two vols. 8vo.

PLINTH, Orle, or *Orlo*, in *Architecture*, a flat square member, in the form of a brick. It is used as the foundation of columns, being that flat square table under the moulding of the base and pedestal at the bottom of the whole order. It seems to have been originally intended to keep the bottom of the original wooden pillars from rotting. Vitruvius also calls the Tuscan abacus *plinth*.

Plinth of a Statue is a base, either flat, round, or square, which serves to support it.

Plinth of a Wall denotes two or three rows of bricks advancing out from a wall; or, in general, any flat high moulding which serves, in a front-wall, to sustain the eaves of a wall, or support the larmier of a chimney.

PLOCK, a province or waiwodschaft of Poland, which has been formed out of the ancient division of that name, and the addition of part of Massovia. It extends in north latitude from 52. 14. to 53. 27., and in east longitude from 18. 39. to 22. 30., and comprehends 6842 square miles. It contains forty-five cities and towns, 3399 villages, with 346,500 inhabitants, of whom 14,000 are Protestants, 24,000 Jews, and the remainder adhere to the Catholic religion. The capital of the province, and of a circle of its name, is the city of Plock. It stands upon the banks of the Vistula, is surrounded with walls, and is the see of a bishop, whose cathedral is here, as well as eleven other churches, and several collegiate and monastic institutions. It contains 960 houses, with 7500 inhabitants, who carry on considerable trade by the river. Long. 19. 42. E. Lat. 52. 33. 3. N.

PLOERMEL, an arrondissement of the department of Morbihan, in France, extending over 682 square miles. It is divided into eight cantons, and these into sixty-one communes, with a population of 84,150 inhabitants. The capital is the city of the same name, situated in a fruitful district, watered by the river Oust. It contains 4720 inhabitants, who carry on manufactures of coarse woollens.

PLOMO, in *Metallurgy*, is a name given by the Spaniards who have the care of the silver mines, to the silver ore when found adhering to the surface of stones, and incrusting their cracks and cavities like small and loose grains of gunpowder. Though these grains be few in number, and the rest of the stone have no silver in it, yet they are always very happy when they find it, as it is a certain token that there is a rich vein somewhere in the neighbourhood. And if in digging forwards they still meet with these grains, or the plomo, in greater quantity, it is a certain sign that they are getting nearer and nearer the good vein.

PLOT, DR ROBERT, a learned antiquary and philosopher, was born at Sutton-Barn, in the parish of Borden, Kent, in the year 1641. He studied in Magdalen Hall, and afterwards in University College, Oxford. In 1682 he was elected secretary of the Royal Society, and published the Philosophical Transactions from No. 143 to No. 166 inclusive. The next year Mr Elias Ashmole appointed him first keeper of his museum, and about the same time the vice-chancellor nominated him primarius professor of chemistry in the university of Oxford. In 1687 he was made secretary to the earl marshal; and the following year received the title of historiographer to James II. In 1690 he resigned his professorship of chemistry, and likewise his place of keeper of the museum, to which he presented a very large collection of natural curiosities, which he had described in his histories of Oxfordshire and Staffordshire; the former published at Oxford in 1677, folio, and reprinted with additions and corrections in 1705, and the latter printed of the same size in 1686. In January 1694–1695, Henry Howard, earl marshal, nominated him Mobray-herald extraordinary; two days after which he was constituted register of the court of honour; and, on the 30th of April 1696, he died of the stone, at his house at Borden.

As Dr Plot delighted in natural history, the above works were designed as essays towards a Natural History of England; and he had actually formed a design of travelling through England and Wales for that purpose. He accordingly drew up a plan of his scheme, in a letter addressed to Bishop Fell, which is inserted at the end of the second volume of Leland's Itinerary, in the edition of 1744. Amongst several manuscripts which he left behind him were large materials for the Natural History of Kent, Middlesex, and the city of London. Besides the above works, he published De Origine Fontium Tentamen Philosophicum, 8vo, and nine papers in the Philosophical Transactions.

PLOTINUS, a Platonic philosopher of the third century. He was born at Lycopolis, a city of Egypt, in 204; and began very early to show a great singularity both in his taste and in his manners. At eight years of age, when he went to school, he used to run to his nurse, and uncover her breast to suck; and would have continued that practice longer if he had not been discouraged by her. At the age of twenty-eight he had a strong desire to study philosophy, on which occasion he was recommended to the most famous professors of Alexandria. He was not satisfied with their lectures; but upon hearing those of Ammonius, he confessed that this was the man he wanted. He studied for eleven years under that excellent master, and then went to hear the Persian and Indian philosophers. In 243, when the Emperor Gordianus intended to wage war against the Persians, he followed the Roman army, but probably repented of it; for it was with difficulty he could save his life by flight after the emperor had been slain. He was then thirty-nine. The year following he went to Rome, and read philosophical lectures in that city; but avoided following the example of Erennius and Origen, his fellow-pupils, who, having like him promised not to reveal some hidden and excellent doctrines which they had received from Ammonius, had nevertheless broken their pledge. Plotinus continued ten years in Rome without writing anything; but in his fiftieth year he obtained as his scholar Porphyry, who, being of an exquisitely fine genius, was not satisfied with superficial answers, but required to have all difficulties thoroughly explained; and therefore Plotinus, to treat things with greater accuracy, was obliged to write more books. He had previously written twenty-one books, and during the six years of Porphyry's sojourn with him he wrote twenty-four, and nine after Porphyry left Rome, making in all fifty-four. The Romans had a high veneration for him; and he passed for a man of such judgment and virtue, that many persons of both sexes, when they found themselves dying, intrusted him, as a kind of guardian angel, with the care of their estates and children. He was the arbiter of numberless lawsuits; and constantly behaved with such humanity and rectitude, that he did not create a single enemy during the twenty-six years he resided in Rome. He did not meet with the same justice, however, from all of his own profession; for Olympias, a philosopher of Alexandria, being envious of his glory, used his utmost endeavours, though in vain, to ruin him. The Emperor Gallienus and the Empress Salonina had a very high regard for him; and if it had not been for the opposition of some jealous courtiers, they would have caused the city of Campania to be rebuilt, and given it to him, with the territory belonging to it, to establish a colony of philosophers, and to govern it according to the ideal laws of Plato's commonwealth. He laboured under various disorders during the last year of his life, which obliged him to leave Rome, when he was carried to Campania, to the heirs of one of his friends, who furnished him with everything necessary; and he died there in the year 270, at the age of sixty-six, in the noblest manner that an heathen philosopher could expire. "I am labouring with all my might," said he, "to return the divine part of me to the Divine Whole which fills the universe."

We have already remarked that the ideas of Plotinus were singular and extraordinary; and we shall now show that they were so. He was ashamed of being lodged in a body, for which reason he did not care to tell the place of his birth or family. The contempt he had for all earthly things was the reason why he would not permit his picture to be drawn; and when his disciple Amelius urged him to do so, "Is it not enough," said he, "to drag after us, whithersoever we go, that image in which nature has shut us up? Do you think that we should likewise transmit to future ages an image of that image, as a sight worthy of their attention?" On the same principle, he refused to attend to his health; for he never made use of preservatives or baths, and did not even eat the flesh of tame animals. He ate but little, and often abstained from bread; which, joined to his intense meditation, prevented him from sleeping. In short, he thought the body altogether below his notice, and had so little respect for it, that he considered it as a prison, from which it would be his supreme happiness to be freed. When Amelius, after his death, inquired of the oracle of Apollo about the state of his soul, he was told that it was gone to the assembly of the blessed, where charity, joy, and a love of the union with God, prevail. And the reason given for this, as related by Porphyry, is, "that Plotinus had been peaceable, gracious, and vigilant; that he had perpetually elevated his spotless soul to God; that he had loved God with his whole heart; that he had disengaged himself, to the utmost of his abilities, from this wretched life; that, elevating himself with all the powers of his soul, and by the several gradations taught by Plato, towards that Supreme Being which fills the universe, he had been enlightened by him, had enjoyed the vision of him without the help or interposition of ideas, and, in short, had often been united to him." This is the account of Porphyry, who also tells us that he himself had once been favoured with the vision. We need scarcely add, however, that little credit is due to such a story, which agrees pretty much with modern enthusiasm and the reveries of Behmenists. Plotinus had his familiar spirit, as well as Socrates; but, according to Porphyry, it was not one of those called *demons*, but of the order of those who are called *gods;* so that he was under the protection of a spirit superior to that of other men. The superiority of his genius puffed him up not a little; or when Amelius desired him to share in the sacrifices which he used to offer up on solemn festivals, "It is their business," replied Plotinus, "to come to me; not mine to go to them."

Porphyry put the fifty-four books of Plotinus in order, and divided them into six nonades. The greater part of them turn on the most high-flown ideas in metaphysics; and this philosopher seems, in certain points, to differ but little from Spinoza. He wrote two books to prove that all being is one and the same; which is, in fact, the very doctrine of Baruc Spinoza. He inquires, in another book, whether there are many souls, or only one. His manner of composing partook of the singularity of his nature. He never read over his compositions after he had written them; he wrote a bad hand, and was not exact in his orthography; he stood in need, therefore, of a faithful friend to revise and correct his writings; and he chose Porphyry for this purpose in preference to Amelius, who had been his disciple twenty-four years, and was very much esteemed by him. Some have accused Plotinus of plagiarism with regard to Numenius; a slander which Amelius refuted. Longinus was once much prejudiced against this philosopher, and wrote against his Treatise of Ideas, and against Porphyry's answer in defence of that treatise. He afterwards conceived a high esteem for Plotinus; sought industriously for all his books; and, in order to have them correct, desired Porphyry to lend him his copy. At the same time he wrote to the latter in the following manner. "I always observed to you, when we were together, when we were at a distance from one another, as well as when you lived at Tyre, that I did not comprehend many of the subjects treated of by Plotinus; but I was extremely fond of his manner of writing, the variety of his knowledge, and the order and disposition of his questions, which are altogether philosophical." This single passage, says Bayle, shows the exalted genius, the exquisite discernment, and judicious penetration of Longinus. It cannot be denied that most subjects which this philosopher examines are incomprehensible; nevertheless, we discover in his works a very elevated, fruitful, and capacious genius, and a close way of reasoning. Had Longinus been an injudicious critic, had he not possessed an exalted and beautiful genius, he would not have been so sensible of Plotinus's obscurity; for no persons complain less of the obscurity of a book, than those whose thoughts are confused, and whose understanding is shallow. Marsilius Ficinus, at the request of Cosmo de' Medici, executed a Latin version of the works of Plotinus, with a summary and analysis of each book; which was printed at Basil, first by itself in 1559, and afterwards with the Greek in 1580, folio. His life was written by Porphyry, the most illustrious of his disciples.

PLOUGH, in *Agriculture*, a machine for turning up the soil by the action of cattle, contrived to save the time, labour, and expense, which must otherwise have been employed in digging the ground, and fitting it for receiving all sorts of seed. See AGRICULTURE.

PLOWDEN, EDMUND, sergeant at law, descended from an ancient family in Shropshire, was born in 1517, and was first a student of the university of Cambridge, where he spent three years in the study of philosophy and medicine. He then removed to Oxford, where, having continued his former studies about four years more, he was in 1552 admitted to the practice of physic and surgery; but probably finding the practice of the healing art less agreeable than the study of physic, he entered himself of the Middle Temple, and began to read law. Wood says, that in 1557 he was summer reader to that society, and Lent reader three years afterwards, being then sergeant and oracle of the law. He died in the year 1584, aged sixty-seven; and was buried in the Temple church. He wrote, 1. Commentaries or Reports of divers Cases in the reigns of Edward VI., Mary, and Elizabeth, London, 1571, 1578, 1599, and 1613, written in the old Norman language; and, 2. Queries, or a Moot-book of Cases, translated, methodized, and enlarged, by H. B. of Lincoln's-Inn, London, 1662, in 8vo.

PLUCHE, ANTONY, a celebrated French writer, was born at Rheims in 1688; and having distinguished himself by his engaging manners and proficiency in the belles lettres, was appointed professor of humanity in the university of that city. Two years afterwards he obtained the chair of rhetoric, and was admitted into holy orders. The Bishop of Leon, informed of his talents, conferred upon him the direction of the college of his episcopal city. By his industry and superior knowledge, a proper order and subordination were soon established in it; but some peculiar opinions respecting the affairs of the time disturbed his tranquillity, and obliged him to resign his office. The intendant of Rouen, at the request of the celebrated Rollin, intrusted him with the education of his son. Abbé Pluche having filled that situation with success and great honour to himself, left Rouen and went to Paris, where, by the patronage of some literary friends, and his own excellent writings, he acquired a distinguished reputation for learning. He published, 1. Le Spectacle de la Nature, in nine volumes 12mo. This work, which is equally instructive and entertaining, is written with perspicuity and elegance; but the form of dialogue which is adopted has rendered it somewhat prolix. The interlocutors are not distinguished by any striking or characteristic features; and though the author has given the conversations a pretty ingenious turn, and even some vivacity, yet now and then they assume the tone of the college. 2. Histoire du Ciel, or History of the Heavens, in two vols. 12mo. In this performance we find two parts almost independent of each other. The first contains some learned inquiries into the origin of the poetical heavens. It is nearly a complete mythology, founded upon ideas which are new and ingenious. The second is the history of the opinions of philosophers respecting the formation of the world. The author shows the inutility, inconsistency, and uncertainty of the most esteemed systems; and concludes with pointing out the excellence and sublime simplicity of the Mosaic account. Voltaire called this work *Fable du Ciel*. 3. De Linguarum Artificio, a work which he translated under the title of Le Mecanique

Plug ‖ Plumbery.

des Langues, in 12mo. In this treatise he proposes a short and easy method of learning languages, which is by the use of translations instead of themes or exercises. 4. Harmony of the Psalms and the Gospel, or a translation of the Psalms and Hymns of the Church, with notes relative to the Vulgate, the Septuagint, and Hebrew Text, printed at Paris in 1764, in 12mo. In 1749, Abbé Pluche retired to Varenne St Maure, where he gave himself up entirely to devotion and study. Having become so deaf that he could not hear without the help of a trumpet, the capital afforded him little enjoyment. It was in this retreat that he died of an apoplexy, on the 20th of November 1761, at the age of seventy-three years. He possessed those qualities which form the scholar, the honest man, and the Christian; temperate in his meals, true to his word, an affectionate parent, a sensible friend, and a humane philosopher, he gave lessons of virtue in his life as well as his writings. His submission to all the dogmas of religion was profound. Some deists having expressed surprise that, in matters of faith, he should think and speak like the vulgar, his answer was, "I glory in doing so; it is infinitely more rational to believe the word of God, than to follow the glimmering lights of a reason which is limited and subject to error."

PLUG, a certain piece of timber, formed like the frustum of a cone, and used to stop a hause-hole, or a breach made in the body of a ship by cannon-balls. Plugs used for the former purpose are therefore called *hause-plugs,* and those for the latter *shot-plugs;* and they are formed of various sizes, in proportion to the holes made by the different sizes of shot which may penetrate the ship's sides or bottom in battle. Accordingly they are always ready for this purpose.

PLUKENET, Leonard, a physician who flourished in the reign of Charles II., was one of the most excellent and laborious botanists of that or any other age. He was author of the Phytographia Plukenetiana, the Almagesticum Britannicum, and other works of a similar kind, on which he spent the greater part of his life and fortune. His Phytography is mentioned with the highest praise in the Philosophical Transactions for February 1696–1697. His Opera Botanica, with cuts, were printed at London, in six vols. folio, in 1720.

PLUMBERY, the art of casting and working lead, and using it in building.

As this metal soon melts, and with little heat, it is easy to cast it into figures of any kind, by running it into moulds of brass, clay, plaster, or other material. But the chief article in plumbery consists of sheets and pipes of lead; and as these form the basis of the plumber's work, we shall here describe the process of making them.

In casting *sheet-lead,* a table or mould is made use of, consisting of large pieces of wood well jointed, and bound with bars of iron at the ends; on the sides of which runs a frame, consisting of a ledge or border of wood, three inches in thickness, and four inches in height from the mould, called the *sharps.* The ordinary width of the mould, within these sharps, is from four to five feet; and its length is sixteen, seventeen, or eighteen feet. This should be something longer than the sheets are intended to be, in order that the end where the metal runs off from the mould may be cut off, because it is commonly thin, or uneven, or ragged, at the end. It must stand very even or level in breadth, and something falling from the end in which the metal is poured in, viz. about an inch or an inch and a half in the length of sixteen or seventeen feet or more, according to the thickness of the sheets wanted; for the thinner the sheet, the more declivity the mould should have. At the upper end of the mould stands the pan, which is a concave triangular prism, composed of two planks nailed together at right angles, and two triangular pieces fitted in between them at the ends. The length of this pan is the whole breadth of the mould in which the sheets are cast. It stands with its bottom, which is a sharp edge, on a form at the end of the mould, leaning with one side against it; on the opposite side is a handle to lift it up by, in order to pour out the melted lead; and on that side of the pan which is next the mould are two iron hooks to take hold of the mould, and prevent the pan from slipping whilst the melted lead is pouring out of it into the mould. This pan is lined on the inside with moistened sand, to prevent it from being fired by the hot metal. The mould is also spread over, about two inches thick, with sand sifted and moistened, which is rendered perfectly level by moving over it a piece of wood called a *strike,* and smoothing it over with a smoothing plane, which is a plate of polished brass about one fourth of an inch thick, and nine inches square, turned up upon all the four edges, and with a handle fitted on to the upper or concave side. The sand being thus smoothed, it is fit for casting sheets of lead. But if they would cast a cistern, they measure out the bigness of the four sides, and having taken the dimensions of the front or fore part, make mouldings by pressing long slips of wood, which contain the same mouldings, into the level sand; and form the figures of birds, beasts, or anything else, by pressing in the same manner leaden figures upon it, and then taking them off, and at the same time smoothing the surface where any of the sand is raised up by making these impressions upon it. The rest of the operation is the same in casting either cisterns or plain sheets of lead. But before we proceed to mention the manner in which that is performed, it will be necessary to give a more particular description of the *strike.*

Plumber

The strike, then, is a piece of board about five inches in breadth, and something longer than the breadth of the mould on the inside; and at each end is cut a notch about two inches deep, so that when it is used it rides upon the sharps with those notches. Before they begin to cast, the strike is made ready by tacking on two pieces of an old hat on the notches, or by slipping a case of leather over each end, in order to raise the under side about one eighth of an inch or something more above the sand, according as they would have the sheet to be in thickness; then the under edge of the strike is tallowed and laid across the mould. The lead being melted, it is put into the pan with ladles, in which, when there is a sufficient quantity for the present purpose, the scum of the metal is swept off with a piece of board to the edge of the pan, letting it settle on the sand, which is by this means prevented from falling into the mould at the pouring out of the metal. When the lead is cool enough, which must be regulated according to the thickness of the sheets wanted, and is known by its beginning to stand with a shell or wall upon the sand round the pan, two men take the pan by the handle, or else one of them lifts it by the bar and chain fixed to a beam in the ceiling, and pour it into the mould, whilst another man stands ready with the strike, and as soon as they have done pouring in the metal, puts on the mould, sweeps the lead forward, and draws the overplus into a trough prepared to receive it. The sheets being thus cast, nothing remains but to roll them up or cut them into any measure wanted. But if it be a cistern, it is bent into four sides, so that the two ends may join the back, where they are soldered together; after which the bottom is soldered up.

We shall next describe the method of casting pipes without soldering. To make these pipes, they have a kind of little mill, with arms or levers to turn it withal. The moulds are of brass, consist of two pieces, which open and shut by means of hooks and hinges, their inward calibre or diameter being, according to the size of the pipe, usually two feet and a half. In the middle is placed a core or round piece of brass or iron, somewhat longer than the mould, and of the thickness of the inward diameter of the pipe. This core is passed through two copper rundles, one at each end of the mould, which they serve to close; and to these is joined a little copper tube about two inches long, and of the thickness the leaden pipe is intended to be of. By means of these tubes the core is retained in the middle of the cavity of the mould. The core being in the mould, with the rundles at its two ends, and the lead melted in the furnace, the latter is taken up in a ladle, and poured into the mould by a little aperture at one end, made in the form of a funnel. When the mould is full, a hook is passed into the end of the core, and, by turning the mill, is drawn out; and after opening the mould, the pipe is also taken out. If they desire to have the pipe lengthened, they put one end of it in the lower end of the mould, and pass the end of the core into it; then shut the mould again, and apply its rundle and tube as before, the pipe just cast serving for a rundle, &c. at the other end. Things being thus replaced, they pour in fresh metal, and repeat the operation till they have got a pipe of the length required.

For making pipes of sheet-lead, the plumbers have wooden cylinders of the length and thickness required; and on these they form their pipes by wrapping the sheet around them, and soldering up the edges all along them.

The lead which lines the Chinese tea-boxes is reduced to a thinness which, we are informed, European plumbers cannot imitate. The following account of the process by which the plates are formed was communicated to a writer in the Gentleman's Magazine, by an intelligent officer of an East Indiaman. The caster sits by a pot containing the melted metal; and has two large stones, the under one fixed, the upper moveable, directly before him. He raises the upper stone by pressing his foot upon the side of it, and with an iron ladle pours in the opening a proper quantity of the fluid metal. He then immediately lets fall the upper stone, and by that means forms the lead into a thin irregular plate, which is afterwards cut into a proper shape. The surfaces of the stones, where they touch each other, are exactly ground together.

PLUMMET, *Plumb-rule*, or *Plumb-line*, an instrument used by carpenters, masons, and others, in order to judge whether walls or beams be upright planes, horizontal, or the like. It is so called from a piece of lead fastened to the end of a cord, which usually constitutes this instrument. Sometimes the string descends along a wooden ruler, raised perpendicularly on another; in which case it becomes a level.

PLUMMING, amongst miners, is the method of using a mine-dial, in order to know the exact place of the work where to sink down an air-shaft, or to bring an adit to the work, or to know which way the lode inclines when any flexure happens in it.

It is performed in this manner. A skilful person, with an assistant, and provided with pen, ink, and paper, a long line, and a mine-dial, after his guess of the place above ground, descends into the adit or work, and there fastens one end of the line to some fixed thing in it; then the incited needle is let to rest, and the exact point where it rests is marked with a pen. The person in question then goes on farther in, the line being still fastened, and at the next flexure of the adit he makes a mark on the line, by a knot or otherwise, and, letting down the dial again, he there likewise notes down that point at which the needle stands in this second position. In this manner he proceeds, from turning to turning, marking down the points, and marking the line, till he comes to the intended place. This being done, he ascends and begins to work on the surface of the earth what he did in the adit, bringing the first knot in the line to such a place where the mark of the place of the needle will again answer its pointing; and continues this till he come to the desired place above ground, which is certain to be perpendicular over the part of the mine into which the air-shaft is to be sunk.

PLUMOSE, something formed in the manner of a feather, with a stem and fibres issuing from it on each side: such are the antennæ of certain moths, butterflies, and other insects.

PLURAL, in *Grammar*, an epithet applied to that number of nouns and verbs which is used when we speak of more than one thing.

PLUS, in *Algebra*, a character marked thus, +, used for the sign of addition. See ALGEBRA.

PLUSH, in commerce, a kind of stuff having a sort of velvet knap or shag on one side, composed regularly of a woof of a single woollen thread and a double warp; the one wool, of two threads twisted, the other goat's or camel's hair; though there are some plushes entirely of worsted, and others composed wholly of hair.

PLUTARCH, one of the most celebrated writers of antiquity, was a native of Chæroneia, in Bœotia. The exact date of his birth and death is unknown; but as he tells us that he studied philosophy under Ammonius at Delphi, when Nero made a tour through Greece, and as we know this circumstance to have taken place A. D. 66, we may place the birth of Plutarch towards the latter years of the reign of Claudius (A. D. 48–53). He was sprung from an honourable family, which had often been invested with the highest offices of the magistracy. He speaks of having seen his great-grandfather Nicarchus, from whom he learned, as from an eye-witness, the miseries which his country had suffered from the oppressions of Antony. His grandfather Lamprias was distinguished for his eloquence and imagination; and his father is praised for his modesty, his acquaintance with the theology of his time, and his knowledge of the works of the poets. Plutarch had two brothers, Timon and Lamprias; of the former of whom he says, that he has no obligations to fortune so great as the enjoyment of his brother Timon's invariable friendship and kindness. Under Ammonius, of whom we know little more than what his pupil has told us, he acquired the doctrines of that humane and rational philosophy for which he was afterwards so distinguished. Upon what occasion he visited Italy is uncertain, but it is supposed to have been on some public business of the Chæroneians. Whilst he remained at Rome, he found his house resorted to by all the principal citizens, and his lectures on philosophy attended by the most illustrious of the Romans. Sossius Senecio, who was four times consul, once under Nerva and thrice under Trajan, was his most intimate friend. To him he addresses his Lives, except that of Aratus, which is inscribed to Polycrates of Sicyon, the grandson of Aratus. Whether he remained in Italy till all philosophers were banished from that country by a decree of Domitian, is a point of which we have no means of determining; but we know that he spent the greater part of his time in his native city. Here he devoted himself to the discharge of such humble duties as the magistrates of Chæroneia were required to perform; and we find that he also joined to his magisterial character the office of priest of Apollo. Suidas states that he was preceptor to Trajan; but he was so nearly contemporary with that emperor, that little credit is due to this assertion. Plutarch was married to a lady of his native city, called Timoxena, and in his matrimonial connection he seems to have been particularly fortunate. By her he had five children, four sons, and a daughter, who died young; and on this occasion he addressed a beautiful letter of consolation to his wife, which is highly honourable to both parties. Two only of his sons survived, Plutarch and Lamprias, the latter of whom appears to have been a philosopher; and it is to him that we are indebted for a catalogue of his father's writings. His nephew Sextus was of considerable eminence, and taught the Greek language to Marcus Antoninus. We have no particular account either as to the manner or the time of his death, only it is evident that he lived to a good old age. The most probable conjecture is that of Fabricius, who says he died in the fifth year of Hadrian, at the age of seventy.

His works have been divided, and they admit of a pretty equal division, into Lives and Morals; the former of which, in his own estimation, were to be preferred, as more noble than the latter. His style has been excepted to with some reason. He has also been criticised for some mistakes in Roman antiquities, and for a partiality to the Greeks. On the other hand, he has been justly praised for the copiousness of his fine sense and learning, for his integrity, and for a certain air of goodness which appears in all he wrote. His business was not to please the ear, but to instruct and charm the mind; and in this none ever excelled him. Of his moral writings it is to be regretted that we have no good English translation. An English version of his Lives, executed with fidelity and spirit, was presented to the public by the Langhornes in 1770. The best edition of his works is that of Reiske, in twelve volumes 8vo, 1774–82.

PLUTO, in Pagan worship, the king of the infernal regions, was the son of Saturn and Ops, and the brother of Jupiter and Neptune. This deity, finding himself childless and unmarried, mounted his chariot to visit the world; and, arriving in Sicily, fell in love with Proserpine, whom he saw gathering flowers with her companions in the valley of Enna, near Mount Ætna; when, forcing her into his chariot, he drove her to the river Chemarus, through which he opened for himself a passage back to the realms of night.

Pluto is usually represented in an ebony chariot drawn by four black horses, sometimes holding a sceptre, to denote his power; at others, a wand, with which he drives away the ghosts; and at others, some keys, to signify that he had the keys of death. Homer observes, that his helmet had the quality of rendering the wearer invisible, and that Minerva borrowed it in order to remain concealed from Mars when she fought against the Trojans. Pluto was greatly revered both by the Greeks and Romans, who erected to him both temples and altars. To this god sacrifices were offered in the night, and it was not lawful to offer them by day.

PLUTUS, in Pagan worship, the god of riches, is frequently confounded with Pluto. He was represented as appearing lame when he approached, but provided with wings at his departure, to show the difficulty of amassing wealth and the uncertainty of its enjoyment. He was also represented blind, to show that he often bestowed his favours on the most unworthy, and left in necessity those who had the greatest merit.

PLUVIUS, a surname of Jupiter. He was invoked by that name amongst the Romans whenever the earth was parched by continual heat, and in want of refreshing rains. He had an altar in the temple on the Capitol.

PLYERS, in fortification, denotes a kind of balance used in raising or letting down a drawbridge. They consist of two timber levers, twice as long as the bridge they lift, joined together by other timbers, framed in the form of a St Andrew's cross, to counterpoise them. They are supported by two upright jambs, on which they swing; and the bridge is raised or let down by means of chains joining the ends of the plyers and bridge.

PLYING, in nautical language, the act of making, or endeavouring to make, a progress against the direction of the wind. Hence a ship that advances well in her course in this manner of sailing, is said to be a good plyer.

PLYMOUTH, a town at the western extremity of the county of Devon, on the southern shore of England. It is a place which has grown to its present importance from the natural advantages of maritime access, and the capability of defence arising from local circumstances, which have been extended by liberal expenditure under the direction of men of the most scientific attainments.

The entrance to the harbour, or more properly harbours, of Plymouth, is not without its dangers, consisting of rocks and shoals. Of the former are the *Mewstone*, the *Shagstone*, and the *Renny*; and of the latter the *Tinker*, the *Shovel*, the *Knap*, and the *Panther*; but their position is so well known, and so accurately pointed out by buoys, that in all but the most tempestuous and foggy weather they are easily avoided, and fewer accidents to ships occur here than in almost any other harbour. The first object deserving notice in the water-access to Plymouth is that part called the *Sound*, a most capacious anchoring place, capable of affording shelter and protection to fifty sail of the line. The Sound has been rendered secure by that prodigious display of human labour known by the name of the *Breakwater*. As a full and scientific description of that work has been given in a former volume (see vol. v. page 219), we refer to it; only adding, that since the trial of the storms of 1816 and 1817, the strength as well as the utility of the work has been proved by a storm which took place on the 23d of November 1824, when the whole southern coast of England was bestrewed with wreck and desolation. The tide then rose to the frightful height of twenty-six feet two inches, whilst the mean rise of its height at spring-tides is usually only eighteen feet. The greater part of the surface of the Breakwater was on that occasion completely overturned, and huge stones of from two to five tons each were carried from the outer and deposited on the inner slope. The centre and western ends suffered most, and the landing-place was destroyed. It is, however, considered that the advantage gained to the work by the shock, causing the blocks to settle down more firmly, will amply compensate for the derangement of the surface. On the whole, therefore, this occurrence may be considered as a most satisfactory proof of the utility and durability of this national barrier. It need scarcely be remarked, that those liabilities to injury to which such a work as the Breakwater is subject whilst in progress, will not exist in an equal degree when the work is completed. Thus, in a hurricane of January 1828 not a single stone of the finished part of the work was removed from its position. The fears entertained by some persons that the erection might ultimately prove detrimental to the Sound and to the harbour within, by causing an increased deposit of mud and silt, are satisfactorily proved to be groundless; no perceptible alteration having taken place in the depth of water in any of those places, or any change in the strength or the set of the tides.

Within the Breakwater there are many indentations, the mouths of which terminate in the *Sound*, and form excellent harbours, some of them adapted for the largest class of ships. The easternmost of these inlets is at first called Catwater, and extends to the Lake of Saltram, being crossed by the Lary Bridge, an elegant work, erected between the years 1824 and 1827, about 500 feet in length. The small river Plym, which gives its name to the town, empties its water into the Lake of Saltram. It is a stream of short course, rising from the Dartmoor Mountains. The next to Catwater is a capacious harbour, called Sutton Pool, which is capable of receiving a thousand sail. It is used chiefly by the largest class of merchant-ships, and by the steam-packets; and it has several yards for repairing or building merchant-vessels. The next harbour is called Mill Bay; it is chiefly used for commercial purposes, and has some good quays, some ship-building yards, and good moorings for steam-boats. Beyond that, at the extreme west, which it separates from Cornwall, is that indentation which is of the most importance to the British navy. It is the harbour of Hamoaze, one of the finest in the world. It is open to the full force of the tide, but receives the stores of fresh water which fall into it from the rivers Tavy, Tamar, Lynher, and St Germains. It is the place where the men of war in ordinary are moored; and on its border are the extensive dock-yard, the gun-wharf, and the powder-magazine, which, with other objects, will hereafter be noticed. In Hamoaze, the admiral commanding the port has the flag displayed on his ship; and when surrounded, as he commonly is, by a hundred sail of vessels, a most impressive spectacle is presented to view afloat, whilst the picturesque objects on the shore tend to increase the effect.

Within the Breakwater is an island, sometimes called Drake's, sometimes St Nicholas'. It is surrounded with rocks, has a strong castle and other fortifications, and is provided with furnaces for heating balls, and with other means of defence; and it is of great importance, as commanding the entrance into Hamoaze, Catwater, and the other harbours.

Little is known of Plymouth prior to the time of the Norman conquest, when it was called South Town or Sutton. In the reign of Edward I. it was called Sutton Prior and Sutton Valletort, the northern parts being situated on the lands of the prior of Plympton, and the southern parts on the estates of the Valletorts. At that period it was chiefly inhabited by fishermen. Under the fostering care of the priors the place made considerable advances, and the more appropriate name of Plym-mouth was given to it. The growing prosperity of the town excited the jealousy of France; and in 1389 a force from thence landed and attempted to burn it. They succeeded in burning a portion, but were ultimately repulsed, with the loss of 500 men, by Hugh Courtenay. Similar attempts were subsequently made at various times, but with no great result; and after each, the fortifications were extended and strengthened. During the civil war between Charles I. and the parliament, Plymouth was held by the troops of the latter party, who, though besieged, and almost reduced by famine, resisted for three years every effort of the royalists. After the restoration, the citadel was erected; and in the reign of William III. the dock-yard and the naval arsenal were established towards the west, upon the eastern shore of Hamoaze. Since that time it has gone on increasing; but the greatest progress has been made during the present century, in which it has assumed a new character, in the intelligence and wealth of the inhabitants, as well as in the architectural style of its buildings both public and private. The buildings collectively called Plymouth are comprehended in three divisions, now known, the first by that name, the second by that of Stonehouse, and the third by that of Devonport. The name of the latter was till August 1824 Plymouth-Dock, when, on an application from the inhabitants, the present name was given by royal authority, on which occasion a column of 125 feet in height was erected to commemorate the introduction of the new name.

The population of the three ports, at the respective decennial enumerations, has been as follows:

	1801.	1811.	1821.	1831.
Plymouth.........	16,040	20,803	21,591	31,080
Stonehouse......	3,407	5,174	6,043	9,571
Devonport.......	23,747	30,083	33,578	34,883
	43,194	56,060	61,212	75,534

Presuming, as we fairly may, that the increase between 1831 and the present time (1838) has been at the same rate as in the preceding periods, the actual population will be upwards of 85,000, or nearly double of what it was thirty-six years ago.

Plymouth was incorporated as a borough in the year 1439, and by that charter, and subsequent alterations of a trifling nature, was governed till 1835, when, by the law made to reform municipal corporations, it was divided into six wards, each choosing six councillors, who elect twelve aldermen, out of which one is appointed mayor; and, besides the mayor, it has six justices of the peace, who are nominated by the king. Two members for this borough are returned to the House of Commons. The town is in the hundred of Roborough, and consists of two parishes, which are within the deanery of Plympton and the archdeaconry of Totness, in the diocese of Exeter. The church of the parish of St Andrews is interesting to the admirers of ancient architecture. It formerly belonged to a monastery; and many alterations having been made since its erection in 1440, various styles are exhibited in the building, which thus as a whole appears incongruous; and, though handsome in parts, it wants, as regards the body of the church, that altitude which is the most essential ingredient of Gothic architecture. The windows are of the pointed style. The tower, containing a fine peal of eight bells, must be admitted to be of good general proportions, and it is crowned by a pinnacled compartment of remarkable beauty.

The other church, of the parish of Charles, was built in the reign of the first king of that name. The tower and spire have an agreeable outline, but otherwise the exterior of the building can only be described as in the debased Gothic style of a degenerate period. Each of these churches has a chapel attached to it, under the respective clergymen, which together contain sittings for 2700 persons. There are two other episcopal chapels, one in the citadel and the other on the Hoe, which afford sittings for about 3000 persons. The several sects of Methodists, Baptists, Independents, Quakers, Roman Catholics, and Unitarians, have their respective places of religious worship; but the first mentioned have by far the most numerous body of adherents. The Hoe or Howe at Plymouth is an eminence on the south side of the town. It is a healthful and pleasing promenade, stretching from Catwater to Mill Bay, on the eastern extremity of which is built the principal defence of this most important place, called the Citadel. The entrance to this work, on the side of the town, is through two gateways of a bad specimen of architecture. The buildings consist of houses for the governor and other officers, of barracks, an hospital, a magazine, an armoury, and a chapel. The fortification consists of three regular and two irregular bastions; the curtains of the regular bastions being strengthened by two ravelins and horn-works; on the east, north, and west sides are a deep ditch, counterscarp, and covered way, palisadoed, and the parapets are pierced for 120 cannon. The lower fort is connected with the Citadel, and is chiefly intended to defend the Sound.

Amongst the public buildings of Plymouth, the most imposing is a noble pile, which comprehends the royal hotel, the assembly-rooms, and the theatre. The foundation was laid in September 1811; and the expense of the erection, amounting to L.60,000, was defrayed partly by the corporation and partly by the institution of a tontine.

The theatre is constructed with not less regard to the safety than to the accommodation of the audience. The roof and entire frame-work of the boxes are of iron, and the auditorium is of a magnitude fully equal to the purpose of the legitimate drama.

The Athenæum is a fine building erected by the Philosophical Institution, and completed in the year 1819. The portico exhibits four columns appropriate to the character of a building devoted to literature and art. In connection with the institution a public library has been established, the building of which exhibits great taste and judgment.

The custom-house, a recent building, is worthy of the town, and convenient for its commerce. It exhibits a front of granite, suitable, solid, and well proportioned. The interior is well arranged for business. On the ground floor are the offices of the principal surveyor, the tide-surveyor, the landing waiter, the searchers, and others. A granite staircase leads to the long room, which is fifty-four feet in length, twenty-six in width, and twenty-two in height. This building was completed in 1820, at an expense of L.8000.

The royal baths is a pile of building between Plymouth and Stonehouse, the appearance of which excites much admiration. It is most appropriately furnished with hot and cold baths of fresh or of sea water, of hot air, of sulphur, and of vapour. The front is in the Doric style of architecture. It has within it a pump-room, where a medicinal water is supplied from a spring, which is chiefly composed of chloride of sodium, muriate of magnesia, and muriate of lime, combined with small proportions of sulphate and carbonate of lime, and a very minute portion of carbonate of iron. It is perhaps the best arranged institution of the kind in England; and the luxuries it provides are administered at very low rates. It belongs to a joint-stock company, incorporated by charter in 1828.

A new public edifice, begun in 1835, for the benevolent purpose of establishing a hospital and dispensary for South Devon and East Cornwall, is approaching to its completion. At present the central part only is erecting; but in the plan it is contemplated to erect two wings, as soon as sufficient funds flow in for the purpose. These would double the capacity of the building as to beds, and supply other conveniences. There are in the centre part a theatre for operations and lectures, and wards for forty beds, with appropriate rooms for nurses and other attendants. Few towns have advanced so much within the last twenty years, in respect to its public buildings, as Plymouth. That advance is still progressive, and new erections are now constructing, one intended as a guild-hall, instead of the old building, another as a new prison, and also one by a society for horticultural and other exhibitions. With all the improvements here noticed, it must be observed, that the principal thoroughfares are irregular in their disposition, and that the most bustling street is the narrowest of the town; and though there are excellent shops of every description, some of them exhibiting fronts of chaste architectural character, yet near them are houses of very antique date and style. The northern part of the town consists of small but neat houses; but the best masses of buildings are at the west end, and they are chiefly occupied by legal, medical, and other professional persons.

Plymouth is, upon the whole, a healthy place. The climate is mild but rainy: whilst frosts are gentle, and snow rarely remains on the ground. It is well supplied with fresh water, which is brought by pipes from a stream on Dartmoor, at twenty-four miles distance, and from a reservoir distributed in the several streets; the annual charge for the supply of water is sixteen shillings for each house. Provisions are uncommonly cheap, and of the best quality. The market for fish is very remarkable, both for the variety, the excellence, and the cheapness of that description of food. The market-days are Mondays, Thursdays, and Saturdays, and the market-place is spacious, comprehending nearly three acres.

The maritime commerce of Plymouth is extensive. A great trade in timber is carried on with the Baltic, with America, and the Mediterranean, and there is a direct intercourse with the West Indies and Mauritius, which secures a good supply of tropical commodities. It is a bonding port for many articles, and especially for tobacco. There are also large importations of timber, hemp, tallow, and other articles, for the use of the dock-yard. The coasting trade is carried on principally with London, Newcastle, Newport in Monmouthshire, and Bristol. Great quantities of manganese are shipped to Scotland, lead to Bristol, and some wool to Hull. The amount of duties paid at the custom-house was, in the year ending 5th January 1836, L.93,462. 3s. 11d., and at 5th January 1837, L.103,423. 7s. 4d. The ships and their tonnage that entered the port in the year ending January 1837, were, British two hundred and nineteen ships, 20,890 tons; and foreign thirty-seven ships, 4779 tons. The whole number of ships owned by Plymouth are three hundred and fifty, the tonnage of which amounts to 30,000 tons. Besides these, there are more than fifty decked boats, called *trawlers*, employed in the extensive fishery at sea, which take such quantities of fish as to enable the captors to send them to Exeter, Bath, and even London. The building and repairing of ships gives occupation to a great number of persons.

Plymouth was in 1834 constituted a stannary town. The neighbouring tin and other mines are numerous and productive. The vicinity also abounds in quarries of granite, slate, and marble; the latter being highly esteemed for its veining and susceptibility of polish. The export of granite and the other stone is much facilitated by the railroad, twenty-four miles in length, which extends from the interior of Dartmoor to the quays of Catwater and Sutton Pool harbours. By the same means coal, lime, and manure are conveyed from the port to the interior. This railroad was executed by a joint-stock company formed in the year 1818, and was completed in 1820. The Exchange for the merchants, erected in 1813, is near the custom-house; and, amongst other institutions, it has a chamber of commerce, a marine insurance office, a steam-packet office, the oil-gas company's office, and an appropriate reading-room.

Plymouth abounds with benevolent institutions, both of ancient and modern foundation, which, from the great number of them, can only be but slightly noticed. The workhouse, a corporate establishment, founded by several acts of parliament, provides for a great number of paupers of both sexes and of all ages. Charles's alms-houses, Joy's alms-houses, the Household of Faith, the new alms-houses, the Mendicity Society, the Female Benevolent Society, and some others, are supported either by bequests, or by voluntary contributions, or by annual subscriptions. Most of the places of worship have schools attached to them; and there are a few endowed schools, and one grammar-school, from whose funds exhibitions are given to students at Oxford. Besides the hospital already noticed, there is a large public dispensary, and an infirmary for diseases of the eye. There is a medical society, with a professional library for the members of the healing art, embracing the entire field of medical literature. In 1815, a law library was established, the members of which consist exclusively of barristers and attorneys. The books are open to the reference of any subscriber to the general library, to whose collection they have been recently united. The amusements of Plymouth are the stage, music, balls, annual races, and, what is more appropriate to the situation, regatta or marine races, in which the assistance of the Naval Yacht Club is afforded.

Stonehous

Stonehouse, the centre town of the group, received the name from Joel de Stonehouse, the lord of this domain in the reign of Henry III. before which it was called Hippeston. It is now descended to the Earl of Mount Edgecumbe, who, by granting leases on liberal terms, has assisted in that great increase of the town which the state of the population at four periods has manifested. These leases are granted on lives, renewable for ever at a fixed fine, and subject to an annual conventional rent. The town is joined with Plymouth by a thoroughfare street, and it occupies nearly the same level. The southern part is most on the increase, and is almost entirely occupied by genteel families, chiefly those of naval and military officers, and other persons holding situations under the government.

Stonehouse was constituted a township by the reform act, and exercises the elective franchise in connection with the borough of Devonport. It is divided into two wards, the east and the west, by the line of Brownlow Street. It is under the jurisdiction of a bench of magistrates, who sit weekly at a town-hall. The poor are under the management of a governor, visitors, and guardians, in a workhouse, attached to which is a prison for vagrants and petty offenders, who are detained till they can be removed by the orders of the magistrates. The chief trade by water is in coals and timber; and the vessels discharge their cargoes on quays in the Pool, in which are accommodations for building ships.

There are two parochial chapels, St George's and St Paul's, besides one in the Royal Naval Hospital, which together provide sittings for 2500 persons, and maintain a large national school. The Roman Catholics, Independents, both kinds of Methodists, and the Baptists, have also places of worship; and most of them have schools for the instruction of those attending the public services of them.

An object that strikes every one in passing from Plymouth into Stonehouse is the establishment of the United Gas Company, at Mill Bay, by which the three towns in a direct line of nearly four miles are supplied with light.

The edifices belonging to the government are the most prominent objects in Stonehouse. One of these, the Marine Barracks, is on the western shore of Mill Bay, where there is a convenient landing-place. The buildings form an oblong square, in front of which are the apartments for the privates, whilst those of the officers are on the two sides. On the west side are the entrance gate and a newly erected guard-house. These barracks are handsomely and regularly built, have an hospital, and accommodate about 1000 men. The mess apartments are spacious and well furnished, and the officers have a very good library.

The Royal Naval Hospital is situated in the north-east part of Stonehouse. This important institution for the reception of sick and wounded marines and seamen was founded in 1762. It occupies a rising ground, and the area of the whole is about twenty-four acres, of which thirteen are formed into a delightful place of exercise-ground for the convalescent patients. It consists of ten buildings, surrounding an extensive quadrangle, each containing six wards calculated to receive sixteen patients; but in cases of emergency the number can be extended to twenty. Thus as many as twelve hundred patients can be accommodated at one time. The vast importance of this establishment may be seen by an authentic account, which shows, that in ten years from 1805 to 1815 no less than 48,452 seamen and marines were received into the hospital, and a very great proportion of them returned again to the service as effective men. The superior officer is of the rank of post-captain in the navy, and has under him two lieutenants. The other officers are a physician, a surgeon, a steward, a dispenser, four hospital-mates, several extra mates, and a chaplain.

The most remarkable object at Stonehouse is one only finished during the last reign, and hence bearing the name of the Royal William Victualling Yard. It is situated close to the shore, upon which a most extensive marine terrace has been constructed, fifty feet broad and nearly 1500 feet in length. It is entered from the land side by a magnificent gateway, under an arch surmounted by a statue of his majesty, and two lateral ways. The whole of the building is of beautiful granite; and the shafts of the columns forming the internal avenue are each of one stone thirty-six feet high. After passing the gateway on the left are the neat granite-fronted residences of the two principal resident officers. On the right is the baking-establishment, comprising a quadrangular range of buildings 250 by 200 feet, enclosing an architectural chimney-shaft of granite 150 feet in height. Further on is the Melville quadrangle, 240 feet square, with its rusticated granite archway (twenty-eight feet high), and the clock-chamber, of the same material, making together an elevation of ninety-five feet, and forming a magnificent centre-piece sixty-one feet in width. Opposite to this is the basin, 250 by 200 feet in extent, surrounded by quays of granite, save where an iron swing-bridge vaults over an opening of forty-five feet into Stonehouse Pool. Answering the great bake-house, on the opposite of the basin, is the brew-house, similar in dimensions and in external character to the former, and having a corresponding chimney-shaft. Passing onwards in a direct line from the entrance, the irregular quadrangle of the cooperage is on the left, and beyond that the Clarence stores, which run along the quay of that name 340 feet. There is also a reservoir for fresh water, elevated above most of the buildings, being fifty feet in height, neatly finished with granite and an iron railing, which contains 7000 tons. The Melville quadrangle includes the offices of the establishment, and, with the Clarence stores, are used as dépôts for wet and dry provisions, and for slops for the seamen. In the brew-house a steam-engine is used in the operation of grinding malt, in mashing, and pumping. A similar engine is employed in the bake-house, where there are twenty-five pair of millstones, affording the means of grinding a thousand bushels of meal in ten hours. In the same period flour is converted in the bake-house into ship-biscuit, to the extent of 2450 pounds weight. The entire premises of this establishment occupy an extent of about thirteen acres, of which one half have been recovered from the sea, and the remainder excavated from the rock, the stone taken from which has been made use of to build a strong wall to defend the whole against the sea.

Devonport.

Devonport, the third town of the group, is divided from Stonehouse by an arm of the sea, or inlet, over which there is now a bridge. It is the most populous of the three; but within the last thirty years there has not been so rapid an increase of the inhabitants of this division as of the other two. It is in the parish of Stoke Damerel; and the ground on which it stands is for the most part the property of the St Aubyn family, whose steward holds a court-leet and a court-baron annually at Michaelmas, when a jury is sworn in, to prevent nuisances, and to appoint and swear in constables. Having been constituted a borough by the reform act, it now returns two members to parliament; but the right of voting for them is also extended to the householders of Stonehouse. The town has neither mayor nor aldermen, but is governed by a board of 150 commissioners, elected chiefly from the inhabitants, vacancies being filled once a year; amongst them are the lord and steward of the manor, the commissioner of the dock-yard, the port-admiral, and some other official men. The act of parliament by which this body is constituted has vested in it the management of the watching, lighting, and cleaning the streets, of the poor, and the power of granting licenses to porters and watermen. The mayor, aldermen, and recorder of the borough of Plymouth and Saltash are also qualified to act on the licensing commission. A bench of resident magistrates hold petty sessions at the town-hall on every Wednesday.

The town of Devonport is supplied with water by a company established by act of parliament 33 George III., which, by means of pipes, have brought a stream of water from the Dartmoor Hills, which winds amongst the hills for thirty-seven miles, when it reaches a reservoir on the higher part of the town, whence it is distributed to the several streets and houses. The streets of the town are clean, and the whole has an appearance of great neatness; and two or three of these streets are of very handsome architecture. Several of the public buildings, though upon a small scale, are distinguished for the classical elegance of their architectural designs. The town-hall is distinguished by a Doric portico, in which the depth of the pronaos, and the elevation of the entrance-door upon a second internal landing, are features exciting great admiration. The columns are twenty-seven feet six inches in height, and the lower diameters five feet six inches. The hall is seventy-five feet in length, forty feet in width, and thirty-one feet in height. Within the building are cells for prisoners, offices for parochial business, and apartments occupied by the Mechanics' Institute. The library is an elegant erection, like the town-hall, of recent construction, having been executed in 1823. The celebrated Denon, on seeing the design for this *façade*, pronounced it the best attempt to appropriate Egyptian architecture to domestic purposes that had ever come under his notice. The institution is designated the Civil and Military Library. It has a news-room, committee-room, and spacious library already containing between 4000 and 5000 volumes, constantly augmenting; and, besides, it possesses a comprehensive and valuable collection of minerals, presented by Sir John St Aubyn.

When the name of Devonport was given to this town, a column was erected to commemorate the grant, which now forms one of its chief architectural ornaments. This noble monument is of granite, fluted, and of Doric proportions; not quite six diameters in height; measuring sixty-five feet four inches from the bottom of the shaft to the top of the capital; and making, with its inferior and crowning pedestals a total altitude of 101 feet. Its height above the street, including the rock on which it stands, is 124 feet. A staircase of 140 steps leads to the gallery, the prospect from which will well repay any one for the labour of ascending to it.

The church of Stoke Damerel, the mother church of this very populous parish, being small, several chapels of ease have been erected. Mount Zion chapel exhibits an ingenious adaptation of Mahommedan architecture to Christian purposes. Though it has a strange, it has also a picturesque appearance; and the interior is capacious and commodious. St Aubyn's chapel is distinguished by its stone spire. It was built by subscription, under an act of parliament, in 1771. St John's chapel was built in the same way, eight years later, at a cost of L.7700. The arrangement of the interior is curiously amphitheatrical. The roof embraces a clear span of seventy feet, the length of the chapel being ninety feet. Besides these episcopal chapels, a large one was built in the dock-yard by government in 1821. It was chiefly intended for the accommodation of the officers, civil, naval, and military, together with the operatives and soldiers belonging to the yard; but it is also open to the public. Besides the established churches, the Calvinist and Arminian Methodists, and the Independents and Baptists, have their places of worship, as well as the smaller sects of the Moravians and the Unitarians or Socinians.

The government-house, on Mount Wise, near the grand parade, commands a southern view, of much beauty. It contains every accommodation for carrying on the military government, and for the family of the governor. The front extends 200 feet. A large brass cannon, at the principal entrance, was taken from the Turks in the engagement of the Dardanelles. The port-admiral's house is near to it, on the north-west side, and comprises all the offices for the transaction of naval business, except that of courts-martial, which are always held on board the flag-ship in Hamoaze. At a short distance from it, on the top of the hill, is the *semaphore*, by which a constant communication is maintained between the office and the flag-ship, and which forms the first of a chain of telegraphs communicating with the Admiralty in London. To illustrate the perfection of the telegraphic system, it will be sufficient to state, that a message has been sent to, and an answer received from London, in fifteen minutes. The parade with its martial pomp and music, and Mount Wise with its charming walks and prospects, form a great source of pleasure to the inhabitants. To these may be added Richmond Walk at the foot of Mount Wise, which leads to the public baths constructed at the joint expense of the navy and ordnance departments, and to the king's stairs, erected for access to the shore in 1820.

The most important object in Plymouth and its vicinity is the dock-yard. In the eighth volume of this work, under the article Docks, is a general description of this establishment, to which the reader is referred. To what is there stated, we may add, that the whole dock-yard extends over seventy-five acres of land, of which about one sixth is the property of the crown, and the remainder of Sir John St Aubyn, under a lease for twenty-one years, renewable every seven years with a fine of L.534. 4s. 6d., and an annual ground-rent of thirty shillings per acre.

The operations carried on within the yard give employment to upwards of 4000 men in time of war, and 1500 in time of peace; and in the latter case the number of individuals depending on it for subsistence exceeds 7000. The chapel of the dock-yard is a fine building, the foundation of which was laid in 1814. The interior is elegantly fitted up. It is one hundred feet in length and seventy-five in breadth, and has a tower with a set of bells. The erection is said to have cost L.24,000. In the year 1834 a police force was established as a civil guard to the dock-yard, consisting of a director, three inspectors, three sergeants, and forty constables.

The gun-wharf is an important part of this naval arsenal, on the north side of the dock-yard. It covers five acres of land. It contains storehouses filled with the various instruments of destruction; vast quantities of muskets, pistols, and cutlasses are deposited in chests or arranged in racks, or on the walls in the form of stars, circles, and crescents. Near these storehouses is the blacksmith's shop, and other buildings used as depositories for gun-carriages, and the implements of the field-train. The intervals between the different edifices are occupied by piles of ordnance belonging to the ships in the harbour, with their respective names painted on the cannon. There are also large quantities of shot arrayed in pyramidical heaps, marked with the number contained in each pile. The vast portion of stores seen here, together with the armoury, form a sight worthy of attention.

Access is granted to the national depositories, on an application to the presiding officer, with the name, residence, and profession of the applicant. (G.)

Plymouth. See New England.

PLYMPTON EARLS, or Plympton Maurice, a borough and market-town of the county of Devon, in the hundred of the same name, 217 miles from London and five from Plymouth. It is one of the stannary towns for stamping tin. It is governed by a mayor, recorder, and seven aldermen, and returned two members to parliament till 1832, when it was disfranchised. The population amounted in 1801 to 604, in 1811 to 715, in 1821 to 762, and in 1831 to 804.

PLYNTERIA, a Grecian festival in honour of Aglauros, or rather of Minerva, who received from the daughter of Cecrops the name of Aglauros. The word is derived from πλυνειν, *lavare*, because during the solemnity they undressed the statue of the goddess and washed it. The day on which it was observed the people looked upon as unfortunate and inauspicious; and therefore no person was permitted to appear in the temples, which were purposely surrounded with ropes. The arrival of Alcibiades in Athens on that day was thought very unfortunate, but the success which ever afterwards attended him proved it to be otherwise. It was customary at this festival to bear in procession a cluster of figs, thus intimating the progress of civilization amongst the primitive inhabitants of the earth, as figs served them for food after they had contracted a dislike for acorns.

PNEUMATICS.

Definition.

According to the present usage of our language, this term is restricted to that part of natural philosophy which treats of mechanical properties of elastic fluids. The word, in its original meaning, expresses a quality of air, or more properly of breath. Under the article Physics we observed, that in a great number of languages the term employed to express breath was also one of the terms used to express the animating principle, nay, the intellectual substance, the soul.

Extent of the science

We have extended the term Pneumatics to the study of the mechanical properties of all elastic or sensibly compressible fluids, that is, of fluids whose elasticity and compressibility become an interesting object of our attention; as the term Hydrostatics is applied to the study of the mechanical properties of such bodies as interest us by their fluidity or liquidity only, or whose elasticity and compressibility are not familiar or interesting, though not less real or general than in the case of air and all vapours.

No precise limit to the different classes of bodies.

There is no precise limit to the different classes of natural bodies with respect to their mechanical properties. There is no such thing as a body perfectly hard, perfectly soft, perfectly elastic, or perfectly incompressible. All bodies have some degree of elasticity intermixed with some degree of ductility. Water, mercury, oil, are compressible; but their compressibility need not be attended to in order perfectly to understand the phenomena consequent on their materiality, fluidity, and gravity. But if we neglect the compressibility of air, we remain ignorant of the cause and nature of its most interesting phenomena, and are but imperfectly informed with respect to those in which its elasticity has no share; and it is convenient to attend to this distinction in our researches, in order to understand those phenomena which depend solely or chiefly on compressibility and elasticity. This observation is important; for here elasticity appears in its most simple form, unaccompanied with any other mechanical affection of matter (if we except gravity), and lies most open to our observation, whether employed for investigating the nature of this very property of bodies, or for explaining its mode of action. We shall even find that the constitution of an avowedly elastic fluid, whose compressibility is so very sensible, will give us the distinctest notions of fluidity in general, and enable us to understand its *characteristic appearances*, by which it is distinguished from solidity, namely, the *equable* distribution of pressure through all its parts in every direction, and the horizontality which its surface assumes by the action of gravity: phenomena which have been assumed as equivalent to the definition of a perfect fluid, and from which all the laws of hydrostatics and hydraulics have been derived. And these laws have been applied to the explanation of the phenomena around us; and water, mercury, oil, &c. have been denominated fluid only because their appearances have been found to tally exactly with these consequences of this definition, while the definition itself remains in the form of an assumption, unsupported by any other proof of its obtaining in nature.

Air the
nost fami-
iar com-
ressible
luid.

Of all the sensible compressible fluids air is the most familiar, was the first studied, and has been the most minutely examined. It has therefore been generally taken as the example of their mechanical properties, whilst those mechanical properties which are peculiar to any of them, and therefore characteristic, have usually been treated as an appendix to the general science of pneumatics.

Different
roperties
f air.

But although the mechanical properties are the proper subjects of our consideration, it will be impossible to avoid considering occasionally properties which are more of a chemical nature; because they occasion such modifications of the mechanical properties as would frequently be unintelligible without considering them in conjunction with the other; and, on the other hand, the mechanical properties produce such modifications of the properties merely chemical, and of very interesting phenomena consequent on them, that these would often pass unexplained unless we give an account of them in this place.

Mechanical properties.

By mechanical properties we mean such as produce, or are connected with, sensible changes of motion, and which indicate the presence and agency of moving or mechanical powers. They are therefore the subject of mathematical discussion; admitting of measure, number, and direction. We shall therefore begin with the consideration of air.

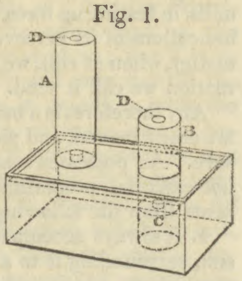
What is air?

It is by no means an idle question to put, What is this air of which so much is said and written? We see nothing, we feel nothing of it. We find ourselves at liberty to move about in any direction without any obstacle or hinderance. Whence, then, the assertion, that we are surrounded with a matter called air? A few very simple observations and experiments will show us that this assertion is well founded.

Proofs that it is matter

We are accustomed to say, that a vessel is empty when we have poured out of it the water which it contained. Take a cylindrical glass jar, having a small hole in its bottom; and having stopped this hole, fill the jar with water, and then pour out the water, leaving the glass empty, in the common acceptation of the word. Now, throw a bit of cork, or any light body, on the surface of water in a cistern; cover this with the glass jar A held in the hand with its bottom upwards, and move it downwards, as at B, keeping it all the while in an upright position. The cork will continue to float on the surface of the water in the inside of the glass, and will most distinctly show whereabouts that surface is. It will thus be seen, that the water within the glass has its surface considerably lower at C than that of the surrounding water; and however deep we immerge the glass, we shall find that the water will never rise in the inside of it so as to fill it. If plunged to the depth of 32 feet, the water will only half fill it; and yet the acknowledged laws of hydrostatics tell us, that the water would fill the glass if there were nothing to hinder it. There is therefore something already within the glass which prevents the water from getting into it; manifesting in this manner the most distinctive property of matter, viz. the hindering other matter from occupying the same place at the same time.

Fig. 1.



Possessed of impulsive force,

While things are in this condition, pull the stopper D out of the hole in the bottom of the jar, and the water will instantly rise in the inside of the jar, and stand at an equal height within and without. This is justly ascribed to the escape through the hole of the matter which formerly obstructed the entry of the water; for if the hand be held before the hole, a puff will be distinctly felt, or a feather held there will be blown aside; indicating in this manner that what prevented the entry of the water, and now escapes, possesses another characteristic property of matter, *impulsive force*. The materiality is concluded from this appearance, in the same manner that the materiality of water is concluded from the impulse of a jet from a pipe. We also see the mobility of the formerly pent up, and now liberated substance, in consequence of external pressure, viz. the pressure of the surrounding water.

Impenetrability,

Also, if we take a smooth cylindrical tube, shut at one end, and fit a plug or cork to its open end, so as to slide along it, but so tightly as to prevent all passage by its sides; and if the plug be well soaked in grease, we shall find that no force whatever can push it to the bottom of the tube. There is therefore something within the tube preventing by its impenetrability the entry of the plug, and therefore possessing this characteristic of matter.

Elasticity,

In like manner, if, after having opened a pair of common bellows, we shut up the nozzle and valve hole. and try to bring the boards together, we find it impossible There is something included which prevents this, in the same manner as if the bellows were filled with wool; but on opening the nozzle we can easily shut them, viz. by expelling this something; and if the compression be forcible, the something will issue with considerable force, and very sensibly impel any thing in its way.

Inertia, and mobility.

It is not accurate to say, that we move about without *any* obstruction: for we find, that if we endeavour to move a large fan with rapidity, a very sensible hinderance is perceived, and a sensible wind is produced, which will agitate the neighbouring bodies. It is therefore justly concluded that the motion is possible only in consequence of having driven this obstructing substance out of the way; and that this impenetrable, resisting, moveable, impelling substance, is matter. We perceive the perseverance of this matter in its state of rest when we wave a fan, in the same manner that we perceive the inertia of water when we move a paddle through it. The effects of wind in impelling our ships and mills, in tearing up trees, and overturning buildings, are equal indications of its perseverance in a state of motion. To this matter, when at rest, we give the name air; and when it is in motion we call it wind.

Air a material fluid.

Air, therefore, is a material fluid; a fluid, because its parts are easily moved, and yield to the smallest inequality of pressure. Air possesses some others of the very general, though not essential, properties of matter. It is heavy. This appears from the following facts.

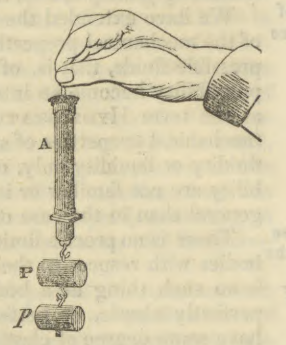
1. It always accompanies this globe in its orbit round the sun, surrounding it to a certain distance, under the name of atmosphere, which indicates the being connected with the earth by its general force of gravity. It is chiefly in consequence of this that it is continually moving round the earth from east to west; forming what is called the trade-wind, to be more particularly considered afterwards. All that is to be observed on this subject at present is, that, in consequence of the disturbing force of the sun and moon, there is an accumulation of the air of the atmosphere, in the same manner as of the waters of the ocean, in those parts of the globe which have the moon near their zenith or nadir: and as this happens successively, going from the east to the west, by the rotation of the earth round its axis in the opposite direction, the accumulated air must gradually flow along to form the elevation. This is chiefly to be observed in the torrid zone; and the generality and regularity of this motion are greatly disturbed by the changes which are continually taking place in different parts of the atmosphere from causes which are not mechanical.

2. It is in like manner owing to the gravity of the air that it supports the clouds and vapours which we see constantly floating in it. We have even seen bodies of no inconsiderable weight float, and even rise, in the air. Soap bubbles, and balloons filled with inflammable gas, (hydrogen or gas obtained from oil or coal,) rise and float in the same manner as a cork rises in water. This phenomenon proves the weight of the air, in the same manner that the swimming of a piece of wood indicates the weight of the water which supports it.

Familiar proofs of its weight.

3. But we are not left to these refined observations for the proof of the air's gravity. We observe many familiar phenomena, which must be immediate consequences of the supposition that air is a heavy fluid, and, like other heavy fluids, presses on the outsides of all bodies immersed in or surrounded by it. Thus, for instance, if we shut the nozzle and valve hole of a pair of bellows after having squeezed the air out of them, we shall find that even some hundred pounds, are necessary for separating the boards. They are kept together by the pressure of the heavy air which surrounds them in the same manner as if they were immersed in water. In like manner, if we stop the end of a syringe after its piston has been pressed down to the bottom, and then attempt to draw up the piston, we shall find a considerable force necessary, viz. about fifteen or sixteen pounds for every square inch of the section of the syringe. Exerting this force, we can draw up the piston to the top, and we can hold it there; but the moment we cease acting, the piston rushes down and strikes the bottom. It is called a suction, as we feel something as it were drawing in the piston; but it is really the weight of the incumbent air pressing it in. And this obtains in every position of the syringe; because the air is a fluid, and presses in every direction. Nay, it presses on the syringe as well as on the piston; and if the piston be hung by its ring on a nail, the syringe requires force to draw it down, just as much as to draw the piston up; and if it be let go, it will spring up unless loaded with at least fifteen pounds for every square inch of its transverse section. See fig. 2.

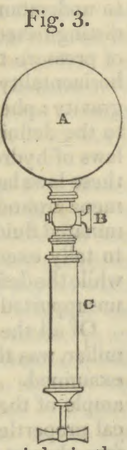
Fig. 2.



It may even be weighed.

4. But the most direct proof of the weight of the air is had by weighing a vessel empty of air, and then weighing it again when the air has been admitted; and this, as it is the most obvious consequence of its weight, has been asserted as long ago as the days of Aristotle. If we take a very large and limber bladder, and squeeze out the air very carefully, and weigh it, and then fill it till the wrinkles just begin to disappear, and weigh it again, we shall find no difference in the weight. But this is not Aristotle's meaning: because the bladder, considered as a vessel, is equally full in both cases, its dimensions being changed. We cannot take the air out of a bladder without its immediately collapsing. But what would be true of a bladder would be equally true of any vessel. Therefore, take a round vessel A, (fig. 3,) fitted with a stopcock B, and syringe C. Fill the whole with water, and press the piston to the bottom of the syringe. Then keeping the cock open, and holding the vessel upright, with the syringe undermost, draw down the piston. The water will follow it by its weight, and leave part of the vessel empty. Now shut the cock, and again push up the piston to the bottom of the syringe, the water escapes through the piston valve, as will be explained afterwards; then opening the cock, and again drawing down the piston, more water will come out of the vessel. Repeat this operation till all the water have come out. Shut the cock, unscrew the syringe, and weigh the vessel very accurately. Now open the cock, and admit the air, and weigh the vessel again, it will be found heavier than before, and this additional weight is the weight of the air which fills it; and it will be found to be 523 grains, about an ounce and a fifth avoirdupois, for every cubic foot that the vessel contains. Now since a cubic foot of water would weigh 1000 ounces, this experiment would show that water is about 840 times heavier than

Fig. 3.



air. The most accurate judgment of this kind of which we have met with an account, is that recorded by Sir George Shuckburgh, in the sixty-seventh volume of the Philosophical Transactions, (p.560.) From this it follows, that when the air is of the temperature 53, and the barometer stands at 29¼ inches, the air is 836 times lighter than water. But the experiment is not susceptible of sufficient accuracy for determining the exact weight of a cubic foot of air. Its weight is very small; and the vessel must be strong and heavy, so as to overload any balance that is sufficiently nice for the experiment.[1]

The most convenient method of doing this.

To avoid this inconvenience, the whole may be weighed in water, first loading the vessel so as to make it preponderate an ounce or two in the water. By this means the balance will be loaded only with this small preponderancy. But even in this case there are considerable sources of error, arising from changes in the specific gravity of the water and other causes. The experiment has often been repeated with this view, and the air has been found at a medium to be about 840 times as light as water, but with great variations, as may be expected from its very heterogeneous nature, in consequence of its being the menstruum of almost every fluid, of all vapours, and even of most solid bodies; all which it holds in solution, forming a fluid perfectly transparent, and of very different density according to its composition. It is found, for instance, that perfectly pure air of the temperature of our ordinary summer is considerably denser than when it has dissolved about half as much water as it can hold in that temperature; and that with this quantity of water the difference of density increases in proportion as the mass grows warmer, for damp air is more expansible by heat than dry air. We have had occasion to consider this subject when treating of the connection of the mechanical properties of air with the state of the weather.

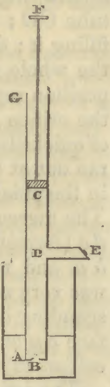
This property of air denied by the Peripatetics.

Such is the result of the experiment suggested by Aristotle, evidently proving the weight of the air; and yet the Peripatetics uniformly refused it this property. It was a matter long debated among the philosophers of the last century. The reason was, that Aristotle assigns a different cause to many phenomena which any man led by common observation would ascribe to the weight of the air. Of this kind is the rise of water in pumps and syphons. Aristotle had asserted that all nature was full of being, and that nature abhorred a void. He adduces many facts, in which it appears, that if not absolutely impossible, it is very difficult, and requires great force, to produce a space void of matter. When the operation of pumps and syphons came to be known, the philosophers of Europe, found in this fancied horror a ready solution of the phenomena. We shall state the facts that every reader may see what kind of reasoning was received not two centuries ago.

Construction of pumps in the last century.

Pumps were then constructed in the following manner: A long pipe GB was set in the water of the well A. This was fitted with a sucker or piston C, having a long rod CF, and was furnished with a valve B at the bottom, and a lateral pipe DE at the place of delivery, also furnished with a valve. The fact is, that if the piston be thrust down to the bottom, and then drawn up, the water will follow it; and upon the piston being again pushed down, the water shuts the valve B by its weight, and escapes or is expelled at the valve E; and on drawing up the piston again the valve E is shut, the water again rises after the piston, and is again expelled at its next descent.

Fig. 4.



The Peripatetics explain all this by saying, that if the water did not follow the piston there would be a void between them. But nature abhors a void; therefore the water follows the piston; this reasoning is overturned by one observation. Suppose the pipe shut at the bottom, the piston can be drawn up, and thus a void produced.

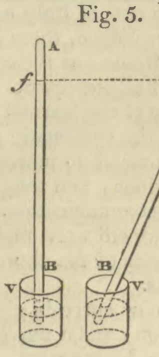
Galileo first predicted the height to which water would rise.

Galileo seems to have been the first who seriously ascribed this to the weight of the air. Many had supposed air heavy; and thus explained the difficulty of raising the board of bellows, or the piston of a syringe, &c. But he distinctly applies to this allowed weight of the air all the consequences of hydrostatical laws; and he reasons as follows. The heavy air rests on the water in the cistern, and presses it with its weight. It does the same with the water in the pipe, and therefore both are on a level: but if the piston, after being in contact with the surface of the water, be drawn up, there is no longer any pressure on the surface of the water within the pipe; for the air now rests on the piston only, and thus occasions a difficulty in drawing it up. The water in the pipe, therefore, is in the same situation as if more water were poured into the cistern, that is, as much as would exert the same pressure on its surface as the air does. In this case we are certain that the water will be pressed into the pipe, and will raise up the water in it, and follow it till it is equally high within and without. The same pressure of the air shuts the valve E during the descent of the piston. He did not wait for the very obvious objection, that if the rise of the water was the effect of the air's pressure, it would also be its measure, and would be raised and supported only to a certain height. He directly said so, and adduced this as a decisive experiment. If the horror of a void be the cause, says he, the water must rise to any extent however great; but if it be owing to the pressure of the air, it will only rise till the weight of the water in the pipe is in equilibrio with the pressure of the air, according to the common laws of hydrostatics. And he adds, that this is well known; for it is a fact, that pumps will not *draw* water much above forty palms, although they may be made to *propel* it, or to *lift it* to any height. He then makes an assertion, which, he says, if true, will be decisive. Let a very long pipe, shut at one end, be filled with water, and let it be erected perpendicularly with the close end uppermost, and a stopper in the other end, and then its lower orifice immersed into a vessel of water; the water will subside in the pipe upon removing the stopper, till the remaining column is in equilibrio with the pressure of the external air. This experiment he proposes to the curious; saying, however, that he thought it unnecessary, there being already such abundant proofs of the air's pressure.

His prediction verified.

It is probable that the cumbersomeness of the necessary apparatus protracted the making of this experiment. Another equally conclusive, and much easier, was made in 1642 after Galileo's death, by his zealous and learned disciple Toricelli. He filled a glass tube, close at one end, with mercury; judging, that if the support of the water was owing to the pressure of the air, and was the measure of this pressure, mercury would in like manner be supported by it, and this at a height which was also the measure of the air's pressure, and therefore thirteen times less than water. He had the pleasure of seeing his expectation verified in the completest manner; the mercury descending in the tube AB, and finally settling at the height

Fig. 5.



---

[1] This method as here stated requires a strong vessel, and consequently overloads a delicate balance; but the objection does not apply when water is not used, and the flask weighed, first when full of air, and again when the air has been exhausted by the air-pump to a known amount; in this way the specific gravity of any gas may be determined.

fB of 29¾ Roman inches: and he found, that when the tube was inclined, the point f was in the same horizontal plane with f in the upright tube, according to the received laws of hydrostatical pressure. The experiment was often repeated, and soon became famous. About three years afterwards the same experiment was published, at Warsaw in Poland, by Valerianus Magnus, as his own discovery: but it appears from the letters of Roberval, not only that Toricelli was prior, and that his experiment was the general topic of discussion among the curious; but also highly probable that Valerianus Magnus was informed of it when at Rome, and daily conversant with those who had seen it. He denies, however, even having heard of the name of Toricelli.

Origin of the Royal Society.

This was the era of philosophical ardour; and we think that it was Galileo's invention and immediate application of the telescope which gave it vigour. Discoveries of the most wonderful kind in the heavens, and which required no extent of previous knowledge to understand them, were thus put into the hands of every person who could purchase a spy-glass; whilst the high degree of credibility which some of the discoveries, such as the phases of Venus and the rotation and satellites of Jupiter, gave to the Copernican system, immediately set the whole body of the learned in motion. About the years 1642 and 1644 we find clubs of gentlemen associated in Oxford and London for the cultivation of knowledge by experiment; and before 1655 all the doctrines of hydrostatics and pneumatics were familiar there, and established by experiment. Mr. Boyle procured a coalition of these clubs under the name of the Invisible and Philosophical Society. In May 1658 Mr. Hooke finished for Mr. Boyle an air-pump, which had employed him a long time, and occasioned him several journeys to London for things which the workmen of Oxford could not execute. He speaks of this as a great improvement on Mr. Boyle's own pump, which he had been using some time before. Boyle therefore must have invented his air-pump, and was not indebted for it to Schottus's account of Otto Guerické's, published in the *Mechanica Hydraulo-pneumatica* of Schottus in 1657, as he asserts *Technica Curiosa.* The Royal Society of London arose in 1656 from the coalition of these clubs, after fifteen years' co-operation and correspondence. The Montmorine Society at Paris had subsisted nearly about the same time; for we find Pascal in 1648 speaking of the meetings in the Sorbonne College, from which we know that society originated. Nuremberg, in Germany, was also a distinguished seminary of experimental philosophy. The magistrates, sensible of its valuable influence in many manufactures, the source of the opulence and prosperity of their city, and many of them philosophers, gave philosophy a professed and munificent patronage, furnishing the philosophers with a copious apparatus, a place of assembly, and a fund for the expence of their experiments; so that this was the first academy of sciences out of Italy under the patronage of government. In Italy, indeed, there had long existed institutions of this kind. Rome was the centre of church-government, and the resort of all expectants for preferment. The clergy was the majority of the learned in all Christian nations, and particularly of the systematic philosophers. Each, eager to recommend himself to notice, brought forward every thing that was curious; and they were the willing vehicles of philosophical communication. Thus the experiments of Galileo and Toricelli were rapidly diffused by persons of rank, the dignitaries of the church, or by the monks their obsequious servants.

Toricellian experiment, repeated in various forms.

All now agree in giving Toricelli the honour of the first invention; and it universally passes by the name of the Toricellian Experiment. The tube is called the Toricellian tube; and the space left by the mercury is called the Toricellian Vacuum, to distinguish it from the Boylean Vacuum, which is only an extreme rarefaction. The experiment was repeated in various forms, and with apparatus which enabled philosophers to examine several effects which the vacuum produced on bodies exposed to it. This was done by making the upper part of the tube terminate in a vessel of some capacity, or communicate with such a vessel, in which were included along with the mercury bodies on which the experiments were to be made. When the mercury had run out, the phenomena of these bodies were carefully observed.

An objection to the conclusion drawn from it obviated.

An objection was made to the conclusion drawn from Toricelli's experiment, which appears formidable. If the Toricellian tube be suspended on the arm of a balance, it is found that the counterpoise must be equal to the weight both of the tube and of the mercury it contains. This could not be, say the objectors, if the mercury were supported by the air. It is evidently supported by the balance; and this gave rise to another notion of the cause different from the Peripatetic *fuga vacui.* A suspensive force, or rather attraction, was assigned to the upper part of the tube.

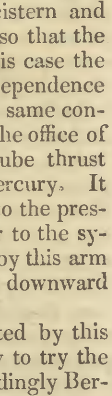
But the true explanation of the phenomena is most easy and satisfactory. Suppose the mercury in the cistern and tube to freeze, but without adhering to the tube, so that the tube could be freely drawn up and down. In this case the mercury is supported by the base, without any dependence on the pressure of the air; and the tube is in the same condition as before, and the solid mercury performs the office of a piston to this kind of syringe. Suppose the tube thrust down till the top of it touches the top of the mercury. It is evident that it must be drawn up in opposition to the pressure of the external air, and it is precisely similar to the syringe in fig. 2. The weight sustained therefore by this arm of the balance is the weight of the tube and the downward pressure of the atmosphere on its top.

Galileo's original experiment performed.

The curiosity of philosophers being thus excited by this very manageable experiment, it was natural now to try the original experiment proposed by Galileo. Accordingly Berti in Italy, Pascal in France, and many others in different places, made the experiment with a tube filled with water, wine, oil, &c., and all with the success which might be expected in so simple a matter: and hence the doctrine of the weight and pressure of the air was established beyond contradiction or doubt. All this was done before the year 1648. A very beautiful experiment was exhibited by Auzout, which completely satisfied all who had any remaining doubts.

A decisive experiment by Auzout.

Fig. 6.



A small box or vial EFGH, had two glass tubes, AB, CD, three feet long, inserted into it in such a manner as to be firmly fixed in one end, and to reach nearly to the other end. AB was open at both ends, and CD was close at D. This apparatus was completely filled with mercury, by unscrewing the tube AB, filling the box and the tube CD; then screwing in the tube AB, and filling it; then holding a finger on the orifice A, the whole was inverted and set upright in the position represented in the figure β, immersing the orifice A (now a of fig. β,) in a small vessel of quicksilver. The result was, that the mercury ran out at the orifice a, till its surface $m\,n$ within the phial descended to the top of the tube $b\,a$. The mercury also began to descend in the tube $d\,c$ (formerly DC,) and run over into the tube $b\,a$, and run out at a, till the mercury in $d\,c$ was very near equal in a level with $m\,n$. The mercury descending in $b\,a$ till it stood at k, 29½ inches above the surface $o\,p$ of the mercury in the cistern, just as in the Toricellian tube.

The rationale of this experiment is very easy. The whole apparatus may first be considered as a Toricellian tube of an uncommon shape, and the mercury would flow out at a. But as soon as a drop of mercury comes out, leaving a space above $m\,n$, there is nothing to keep up the mercury in the tube *d c*. Its mercury, therefore, descends also; and running over into *b a*, continues to supply its expence till the tube *d c* is almost empty, or can no longer supply the waste of *b a*. The inner surface therefore falls as low as it can, till it is level with *b*. No more mercury can enter *b a*, yet its column is too heavy to be supported by the pressure of the air on the cistern below; it therefore descends in *b a*, and finally settles at the height *ko*, equal to that of the mercury in the Toricellian tube.

The prettiest circumstance of the experiment remains. Make a small hole *g* in the upper cap of the box. The external air immediately rushes in by its weight, and now presses on the mercury in the box. This immediately raises the mercury in the tube *d c* to *l*, $29\frac{1}{2}$ inches above *m n*. It presses on the mercury at *k* in the tube *b a*, balancing the pressure of the air in the cistern. The mercury in this tube therefore is left to the influence of its own weight, and it descends to the bottom. Nothing can be more apposite or decisive.

The gravity of the air a statical principle.

And thus the doctrine of the gravity and pressure of the air is established by the most unexceptionable evidence; and we are entitled to assume it as a statical principle, and to affirm *a priori* all its legitimate consequences.

And in the first place, we obtain an exact measure of the pressure of the atmosphere. It is precisely equal to the weight of the column of mercury, of water, of oil, &c. which it can support; and the Toricellian tube, or others fitted up upon the same principle, are justly termed *baroscopes* and *barometers* with respect to the air. Now it is observed that water is supported at the height of 32 feet nearly: the weight of the column is exactly 2000 avoirdupois pounds on every square foot of base, or $13\frac{9}{10}$ on every square inch. The same conclusion very nearly may be drawn from the column of mercury, which is nearly $29\frac{1}{2}$ inches high when in equilibrium with the pressure of the air. We may here observe, that the measure taken from the height of a column of water, wine, spirits, and the other fluids of considerable volatility, as chemists term it, is not so exact as that taken from mercury, oil, and the like. For it is observed, that the volatile fluids are converted by the ordinary heat of our climates into vapour when the confining pressure of the air is removed; and this vapour, by its elasticity, exerts a small pressure on the surface of the water, &c. in the pipe, and thus counteracts a small part of the external pressure; and therefore the column supported by the remaining pressure must be lighter, that is, shorter. Thus it is found, that rectified spirits will not stand much higher than is competent to a weight of 13 pounds on an inch, the elasticity of its vapour balancing about $\frac{1}{13}$ of the pressure of the air. We shall afterwards have occasion to consider this matter more particularly.

A difficulty solved.

As the medium height of the mercury in the barometer is $29\frac{1}{2}$ inches, we see that the whole globe sustains a pressure equal to the whole weight of a body of mercury of this height; and that all bodies on its surface sustain a part of this in proportion to their surfaces. An ordinary sized man sustains a pressure of several thousand pounds. How comes it then that we are not sensible of a pressure which one should think enough to crush us together? This has been considered as a strong objection to the pressure of the air; for when a man is plunged a few feet under water, he is very sensible of the pressure. The answer is by no means so easy as is commonly imagined. We feel very distinctly the effects of removing this pressure from any part of the body. If any one will apply the open end of a syringe to his hand, and then draw up the piston, he will find his hand sucked into the syringe with great force, and it will give pain; and the soft part of the hand will swell into it, being pressed in by the neighbouring parts, which are subject to the action of the external air. If one lays his hand on the top of a long perpendicular pipe, such as a pump filled to the brim with water, which is at first prevented from running out by the valve below; and if the valve be then opened, so that the water descends, he will then find his hand so hard pressed to the top of the pipe, that he cannot draw it away. But why do we only feel the *inequality* of pressure? There is a similar instance wherein we do not feel it, although we cannot doubt of its existence. When a man goes slowly to a great depth under water in a diving-bell, we know unquestionably that he is exposed to a new and very great pressure, yet he does not feel it. But those facts are not sufficiently familiar for general argument. The human body is a bundle of solids, hard or soft, filled or mixed with fluids, and there are few or no parts of it which are empty. All communicate either by vessels or pores; and the whole surface is a sieve through which the insensible perspiration is performed. The whole extended surface of the lungs is open to the pressure of the atmosphere; every thing is therefore in equilibrio; and if free or speedy access be given to every part, the body will not be damaged by the pressure, however great, any more than a wet sponge would be deranged by plunging it any depth in water. The pressure is instantaneously diffused by means of the incompressible fluids with which the parts are filled; and if any parts are filled with air or other compressible fluids, these are compressed till their elasticity again balances the pressure. Besides, all our fluids are acquired slowly, and gradually mixed with that proportion of air which they can dissolve or contain. The whole animal has grown up in this manner from the first vital atom of the embryo. For such reasons the pressure can occasion no change of shape by squeezing together the flexible parts; nor any obstruction by compressing the vessels or pores. We cannot say what would be felt by a man, were it possible that he could have been produced and grown up *in vacuo*, and then subjected to the compression. We even know that any sudden and considerable change of general pressure is very severely felt. Persons in a diving-bell have been almost killed by letting them down or drawing them up too suddenly. In drawing up, the elastic matters within have suddenly swelled, and not finding an immediate escape, have burst the vessels. Dr. Halley experienced this, the blood gushing out from his ears by the expansion of air contained in the internal cavities of this organ, from which there are but very slender passages.

The weather-glass.

A very important observation recurs here. The pressure of the atmosphere is variable. This was observed almost as soon as philosophers began to attend to the barometer. Pascal observed it in France, and Descartes observed it in Sweden in 1650. Mr. Boyle and others observed it in England in 1656. And before this, observers, who took notice of the concomitancy of these changes of aerial pressure with the state of the atmosphere, remarked, that it was generally greatest in winter and in the night; and certainly most variable during winter and in the northern regions. Familiar now with the weight of the air, and considering it as the vehicle of the clouds and vapours, they noted with care the connection between the weather and the pressure of the air, and found that a great pressure of the air was generally accompanied with fair weather, and a diminution of it with rain and mists. Hence the barometer came to be considered as an index not only of the present state of the air's weight, but also as indicating by its variations changes of weather.

The pressure of the air in proportion to the elevation

In the next place, we may conclude that the pressure of the air will be different in different places, according to their elevation above the surface of the ocean; for if air be a heavy fluid, it must press in some proportion according to its perpendicular height. If it be a homogeneous fluid of equal density and weight in all its parts, the mercury in the cistern of a barometer must be pressed precisely in proportion to the depth to which that cistern is immersed in it; and as this pressure is exactly measured by the height of the mercury in the tube, the height of the mercury in the Toricellian tube must be exactly proportional to the depth of the place of observation under the surface of the atmosphere.

This proved by experiments.

The celebrated Descartes first entertained this thought, (Epist. 67. of Pr. III.) and soon after him Pascal. His occupation in Paris not permitting him to try the justness of his conjecture, he requested Mr. Perrier, a gentleman of Clermont in Auvergne, to make the experiment, by observing the height of the mercury at one and the same time at Clermont and on the top of a very high mountain in the neighbourhood. His letters to Mr. Perrier in 1647 are still extant. Accordingly, Mr. Perrier, in September 1648, filled two equal tubes with mercury, and observed the heights of both to be the same, viz. $26\frac{7}{24}$ inches, in the garden of the convent of the Friars Minims, situated in the lowest part of Clermont. Leaving one of them there, and one of the fathers to observe it, he took the other to the top of Puy de Dome, which was elevated nearly 500 French fathoms above the garden. He found its height to be $23\frac{2}{24}$ inches. On his return to the town, in a place called *Font de l'Arbre*, 150 fathoms above the garden, he found it 25 inches; when he returned to the garden it was again $26\frac{7}{24}$, and the person set to watch the tube which had been left, said that it had not varied the whole day. Thus a difference of elevation of 3000 French feet had occasioned a depression of $3\frac{1}{8}$ inches; from which it may be concluded, that $3\frac{1}{8}$ inches of mercury weighs as much as 3000 feet of air, and one-tenth of an inch of mercury as much as 96 feet of air. The next day he found, that taking the tube to the top of a steeple 120 feet high, made a fall of one-sixth of an inch. This gives 72 feet of air for one-tenth of an inch of mercury; but ill agreeing with the former experiment. But it is to be observed, that a very small error of observation of the barometer would correspond to a great difference of elevation, and also that the height of the mountain had not been measured with any precision. This has been since done (Mem. Acad. par. 1703,) and found to be 529 French toises.

Pascal published an account of this great experiment,[1] and it was quickly repeated in many places of the world. In 1653, it was repeated in England by Dr. Power (Power's Exper. Phil.) and in Scotland in 1661, by Mr. Sinclair, professor of philosophy in the university of Glasgow, who observed the barometer at Lanark, on the top of mount Tinto in Clydesdale, and on the top of Arthur's seat at Edinburgh. He found a depression of two inches between Glasgow and the top of Tinto, three quarters of an inch between the bottom and top of Arthur's seat, and $\frac{5}{32}$ of an inch at the cathedral of Glasgow on a height of 126 feet.[2]

Hence a method of measuring heights.

Hence we may derive a method of measuring the heights of mountains. Having ascertained with great precision the elevation corresponding to a fall of one-tenth of an inch of mercury, which is nearly 90 feet, we have only to observe the length of the mercurial column at the top and bottom of the mountain, and to allow 90 feet for every tenth of an inch. Accordingly this method has been practised with great success; but it requires an attention to many things not yet considered; such as the change of density of the mercury by heat and cold; the changes of density of air from its compressibility; a change immediately connected with or dependent on the very elevation we wish to measure.

Also a measure of the density of the air.

These observations give us the most accurate measure of the density of air and its specific gravity. This is but vaguely though directly measured by weighing air in a bladder or vessel. The weight of a manageable quantity is so small, that a balance sufficiently ticklish to indicate even very sensible fractions of it is overloaded by the weight of the vessel which contains it, and ceases to be exact; and when we take Bernouilli's ingenious method of suspending it in water, we expose ourselves to great risk of error by the variation of the water's density. Also it must necessarily be humid air which we can examine in this way: but the proportion of an elevation in the atmosphere to the depression of the column of mercury or other fluid, by which we measure its pressure, gives us at once the proportion of this weight or their specific gravity. Thus since it is found that in such a state of pressure the barometer stands at 30 inches, and the thermometer at 32°, 87 feet of rise produces one-tenth of an inch of fall in the barometer, the air and the mercury being both of the freezing temperature, we must conclude that mercury is 10,440 times heavier or denser than air. Then, by comparing mercury and water, we get $\frac{1}{800}$ nearly for the density of air relative to water; but this varies so much by heat and moisture, that it is useless to retain any thing more than a general notion of it; nor is it easy to determine whether this method or that by actual weighing be preferable. It is extremely difficult to observe the height of the mercury in the barometer nearer than $\frac{1}{200}$ of an inch; and this will produce a difference of even five feet, or $\frac{1}{26}$ of the whole. Perhaps this is a greater proportion than the error in weighing.[3]

Height of the atmosphere.

From the same experiments we also derive some knowledge of the height of the aerial covering which surrounds our globe. When we raise our barometer 87 feet above the surface of the sea, the mercury falls about one-tenth of an inch in the barometer; therefore if the barometer shows 30 inches at the sea-shore, we may expect that, by raising it 300 times 87 feet or five miles, the mercury in the tube will descend to the level of the cistern, and that this is the height of our atmosphere. But other appearances lead us to suppose a much greater height. Meteors are seen with us much higher than this, and which yet give undoubted indication of being supported by our air. There can be little doubt, too, that the visibility of the expanse above us is owing to the reflection of the sun's light by our air. Were the heavenly spaces perfectly transparent, we should no more see them than the purest water through which we see other objects; and we see them as we see water tinged with milk or other fæculæ. Now it is easy to show, that the light which gives us what is called twilight must be reflected from the height of at least 50 miles; for we have it when the sun is depressed 18 degrees below our horizon.

Why this knowledge is not accurate.

A little attention to the constitution of our air will convince us, that the atmosphere must extend to a much greater height than 300 times 87 feet. We see from the most familiar facts that it is compressible; we can squeeze it in an ox-bladder. It is also heavy; pressing on the air in this bladder with a very great force, not less than 1500 pounds. We must therefore consider it as in a state of compression, existing in smaller room than it would assume if it were not compressed by the incumbent air. It must therefore be in a condition something resembling that of a quantity of fine carded wool thrown loosely into a deep pit; the lower strata carrying the weight of the upper strata, and being compressed by them; and so much the more compressed as they are further down, and only the upper stratum in its unconstrained and most expanded state. If we shall suppose this wool thrown in by a hundred weight at a time, it will be divided into strata of equal weights, but of unequal thickness; the lowest being the thinnest, and the superior strata gradually increasing in thickness. Now, suppose the pit filled with air, and reaching to the top of the atmosphere, the weights of all the strata above any horizontal plane in it is measured by the height of the mercury in the Toricellian tube placed in that plane; and one-tenth of an inch of mercury is just equal to the weight of the lowest stratum 87 feet thick; for on raising the tube 87 feet from the sea, the surface of the mercury will descend one-tenth of an inch. Raise the tube till the mercury fall another tenth. This stratum must be more than 87 feet thick: how much more we cannot tell, being ignorant of the law of the air's expansion. In order to make it fall a third tenth, we must raise it through a stratum still thicker; and so on continually.

---

[3] Barometers are now made by which accurate observations may be made to the $\frac{1}{1000}$th part of an inch.

All this is abundantly confirmed by the very first experiment made by the order and directions of Pascal. For by carrying the tube from the garden of the convent to a place 150 fathoms higher, the mercury fell $\frac{7}{24}$ inches, or 1.2916; which gives about 69 feet eight inches of aerial stratum for $\frac{1}{10}$ of an inch of mercury; and by carrying it from thence to a place 350 fathoms higher, the mercury fell $1\frac{22}{24}$, or 1.9167 inches, which gives 109 feet seven inches for $\frac{1}{10}$ of an inch of mercury. These experiments were not accurately made. It is evident, however, from the whole tenor of them, that the strata of air decrease in density as we ascend through the atmosphere; but it remained to be discovered what is the force of this decrease, that is, the law of the air's expansion. Till this be done we can say nothing about the constitution of our atmosphere; we cannot tell in what manner it is fittest for raising and supporting the exhalations and vapours which are continually arising from the inhabited regions; not as an excrementitious waste, but to be supported, perhaps manufactured, in that vast laboratory of nature, and to be returned to us in beneficent showers. We cannot use our knowledge for the curious, and frequently useful, purpose of measuring the heights of mountains and taking the levels of extensive regions; in short, without an accurate knowledge of this, we can hardly acquire any acquaintance with those mechanical properties which distinguish air from those liquids which circulate here below.

Compressibility of the air.

Having therefore considered at some length the leading consequences of the air's fluidity and gravity, let us consider its compressibility with the same care; and then, combining the agency of both, we shall answer all the purposes of philosophy, discover the laws, explain the phenomena of nature, and improve art. We proceed therefore to consider a little the phenomena which indicate and characterise this other property of the air. All fluids are elastic and compressible as well as air; but in them the compressibility makes no figure, or does not interest us while we are considering their pressures, motions, and impulsions. But in air the compressibility and expansion draw our chief attention, and make it a proper representative of this class of fluids.

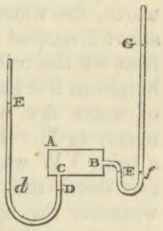
A familiar phenomenon.

Nothing is more familiar than the compressibility of air. It is seen in a bladder filled with it, which we can forcibly squeeze into less room; it is seen in a syringe, of which we can push the plug farther and farther as we increase the pressure. But these appearances bring into view another, and the most interesting, property of air, viz. its *elasticity*. When we have squeezed the air in the bladder or syringe into less room, we find that the force with which we *compressed* it is necessary to *keep it in this bulk;* and that if we cease to press it together, it will swell out and regain its natural dimensions. This distinguishes it essentially from such a body as a mass of flour, salt, or such like, which remain in the compressed state to which we reduce them. There is something therefore which opposes the compression different from the simple impenetrability of the air: there is something that opposes mechanical force: there is something too which produces motion, not only resisting compression, but pushing back the compressing body, and communicating motion to it. As an arrow is gradually accelerated by the bow-string pressing it forward, and at the moment of its discharge is brought to a state of rapid motion; so the ball from a pop-gun or wind-gun is gradually accelerated along the barrel by the pressure of the air during its expansion from its compressed state, and finally quits it with an accumulated velocity. These two motions are indications perfectly similar of the elasticity of the bow and of the air.

Fluidity of the air experimentally proved

Thus it appears that air is heavy and elastic. It needs little consideration to convince us in a vague manner that it is fluid. The ease with which it is penetrated, and driven about in every direction, and the motion of its pipes and channels, however crooked and intricate, entitle it to this character. But before we can proceed to deduce consequences from its fluidity, and to offer them as a true account of what will happen in these circumstances, it is necessary to exhibit some distinct and simple case, in which the characteristic mechanical property of a fluid is clearly and unequivocally observed in it. That property of fluids is, that any pressure applied to any part of them is propagated through the whole mass in every direction; and that in consequence of this diffusion of pressure, any two external forces can be put in equilibrio by the interposition of a fluid, in the same way as they can be put in equilibrio by the intervention of any mechanical engine.

Fig. 7.



Let a close vessel ABC (fig. 7.), of any form, have two upright pipes EDC, GFB, inserted into any parts of its top, sides, or bottom, and let water be poured into them, so as to stand in equilibrio with the horizontal surfaces at E, D, G, F, and let D *d*, F *f*, be horizontal lines, *it will be found* that the height of the column E *d* is sensibly equal to that of the column G *f*. This is a fact universally observed in whatever way the pipes are inserted. Now the surface of the water at D is undoubtedly pressed upwards with a force equal to a column of water, having its surface for its base, and E *d* for its height; it is therefore prevented from rising by some opposite force. This can be nothing but the elasticity of the confined air pressing it down. The very same thing must be said of the surface at F; and thus there are two external pressures at D and F set in equilibrio by the interposition of air. The force exerted on the surface D, by the pressure of the column E *d*, is therefore propagated to the surface at F; and thus air has this characteristic mark of fluidity.

In this experiment the weight of the air is insensible when the vessel is of small size, and has no sensible share in the pressure reaching at D and F. But if the elevation of the point F above D is very great, the column E *d will be observed* sensibly to exceed the column G *f*. Thus if F be 70 feet higher than D, E *d* will be an inch longer than the column G *f*: for in this case there is reacting at D, not only the pressure propagated from F, but also the weight of a column of air, having the surface at D for its base and 70 feet high. This is equal to the weight of a column of water one inch high.

It is by this propagation of pressure, this *fluidity*, that the pellet is discharged from a child's pop-gun. It sticks fast in the muzzle; and he forces in another pellet at the other end, which he presses forward with the rammer, condensing the air between them, and thus propagating to the other pellet the pressure which he exerts, till the friction is overcome, and the pellet is discharged by the air expanding and following it.

Hero's fountain.

There is a philosophical toy which illustrates this property of air, and which we shall have occasion to consider as converted into a useful hydraulic machine. This is what is usually called *Hero's fountain*. It consists of two vessels KLMN (fig. 8.), OPQR, which are close on all sides. The tube AB, having a funnel a-top, passes through the uppermost vessel without communicating with it, being soldered into its top and bottom. It also passes through the top of the under-vessel, where it is also soldered, and reaches almost to its bottom. This tube is open at both ends. There is another open tube ST, which is soldered into the top of the under vessel and the bottom of the upper vessel, and reaches almost to its top. These two tubes serve also to support the upper vessel. A third tube GF is soldered into the top of the upper vessel, and reaches almost to its bottom. This tube is open at both ends, but the orifice G is very small. Now suppose the uppermost vessel filled with water to the height EN, E *e* being its surface a little below T. Stop the orifice G with the finger, and pour in water at A. This will descend through AB, and compress the air in OPQR into less room. Suppose the water in the under vessel to have acquired the surface C *c*, the air which formerly occupied the whole of the spaces OPQR, and KL*e*E will now be contained in the spaces *o* P *c* C and KL *e* E; and its elasticity will be in equilibrio with the weight of the column of water, whose base is the surface E *e*, and whose height is A *c*. As this pressure is exerted in every part of the air, it will be exerted on the surface E *e* of the water of the upper vessel; and if the pipe FG were continued upwards, the water would be supported in it to an height *e*H above E *e*, equal to A *c*. Therefore if the finger be now taken from off the orifice G, the water will spout up to the same height as if it had been immediately forced out by a column of water A *c* without the intervention of the air, that is, nearly to H. If instead of the funnel at A, the vessel have a brim VW which will cause the water discharged at G to run down the pipe AB, this fountain will play till all the water in the upper vessel is expended. The operation of this second fountain will be better understood from fig. 9, which an intelligent reader will see is perfectly equivalent to fig. 8. A very powerful engine for raising water upon this principle has long been employed in the Hungarian mines; where the pipe AB is about 200 feet high, and the pipe FG about 120; and the condensation is made in the upper vessel, and communicated to the lower at the bottom of the mine, by a long pipe.

Fig. 8.

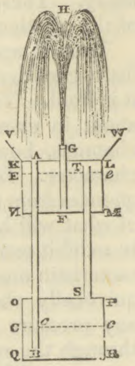


Fig. 9.

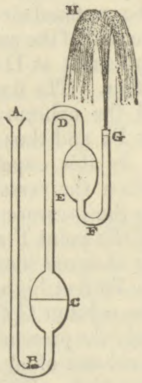


Laws of hydrostatics applicable to air.

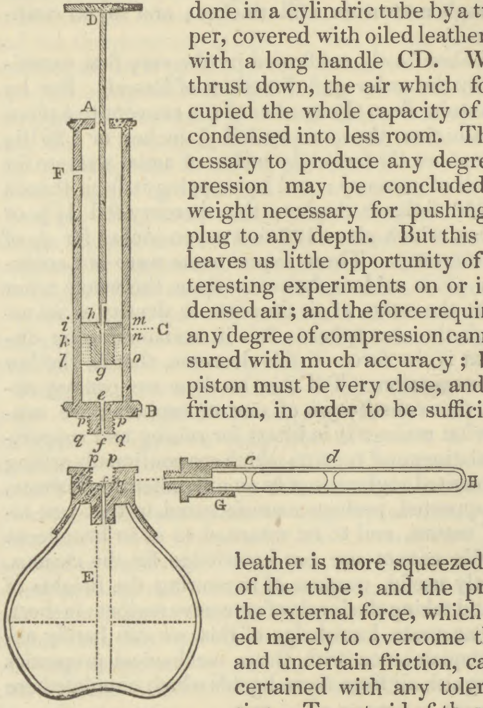
We may now then apply to air the laws of hydrostatics and hydraulics, in perfect confidence that their legitimate consequences will be observed in all its situations. We shall in future substitute, in place of any force acting on a surface of air, a column of water, mercury, or any other fluid whose weight is equal to this force; and as we know distinctly from theory what will be the consequences of this hydrostatic pressure, we shall determine *a priori* the phenomena in air; and in cases where theory does not enable us to say with precision what is the effect of this pressure, experience informs us in the case of water, and analogy enables us to transfer this to air.

More refined experiments

From such familiar and simple observations and experiments, the fluidity, the heaviness, and elasticity, are discovered of the substance with which we are surrounded, and which we call *air*. But to understand these properties, and completely to explain their numerous and important consequences, we must call in the aid of more refined observations and experiments, which even this scanty knowledge of them enables us to make; we must contrive some methods of producing with precision, any degree of condensation or rarefaction, of employing or excluding the gravitating pressure of air, and of modifying at pleasure the action of all its mechanical properties.

Nothing can be more obvious than a method of compressing a quantity of air to any degree. Take a cylinder or prismatic tube AB (fig. 10.) shut at one end, and fit it with a piston or plug C, so nicely that no air can pass by its sides. This will be best done in a cylindric tube by a turned stopper, covered with oiled leather, and fitted with a long handle CD. When this is thrust down, the air which formerly occupied the whole capacity of the tube is condensed into less room. The force necessary to produce any degree of compression may be concluded from the weight necessary for pushing down the plug to any depth. But this instrument leaves us little opportunity of making interesting experiments on or in this condensed air; and the force required to make any degree of compression cannot be measured with much accuracy; because the piston must be very close, and have great friction, in order to be sufficiently tight. And as the compression is increased, the leather is more squeezed to the side of the tube; and the proportion of the external force, which is employed merely to overcome this variable and uncertain friction, cannot be ascertained with any tolerable precision. To get rid of these imperfections, the following addition may be made to the instrument, which then becomes what is called the condensing syringe.

Fig. 10.



The end of the syringe is perforated with a very small hole *e f*, and being externally turned to a small cylinder, a narrow slip of bladder, or of waxed silk, must be tied over the hole at *f*. Now let us suppose the piston pushed down to the bottom of the barrel, to which it applies close; when it is drawn up to the top, it leaves a void behind, and the weight of the external air presses on the slip of bladder, which therefore clasps close to the brass, and thus performs the part of a valve, and keeps it close, so that no air can enter. But the piston having reached the top of the barrel, a hole F in the side of it is just below the piston, and the air rushes through this hole, and fills the barrel. Now push the piston down again, it immediately passes the hole F, and no air escapes through it; it therefore forces open the valve at *f*, and escapes while the piston moves to the bottom.

Now let E be any vessel, such as a glass bottle, having its mouth furnished with a brass cap firmly cemented to it, having a hollow screw which fits a solid screw *p p*, turned to the cylindric nozzle of the syringe. Screw the syringe into this cap, and it is evident that the air forced out of the syringe will be accumulated in this vessel; for upon drawing up the piston, the valve *f* always shuts by the elasticity or expanding force of the air in E; and on pushing it down again, the valve will open as soon as the piston has got so far down that the air in the lower part of the barrel is more powerful than the air already in the vessel. Thus at every stroke an additional barrelful of air will be forced into the vessel E; and it will be found, that after every stroke the piston must be farther pushed down before the valve will open. It cannot open till the pressure arising from the elasticity of the air condensed in the barrel, is superior to the elasticity of the air condensed in the vessel; that is, till the condensation of the first, or its density, is *somewhat* greater than that of the last, in order to overcome the straining of the valve on the hole, and the sticking occasioned by the clammy matter employed to make it air-tight.

Sometimes the syringe is constructed with a valve in the piston. This piston, instead of being of one piece, and solid, consists of two pieces perforated. The upper part *i k n m*, is connected with the rod or handle, and has its lower part turned down to a small cylinder, which is screwed into the lower part *k l o n*, and as a perforation *g h* going up in the axis, and terminating in a hole *h* in one side of the rod, over this hole at *g* there is a valve similar to the valve at *f*. When the piston is drawn up, and a void left below it, the weight of the external air forces it through the hole *g h*, opens the valve *g*, and fills the barrel. Then, on pushing down the piston, the air being squeezed into less room, presses on the valve *g*, shuts it; and none escaping through the piston, it is gradually condensed as the piston descends, till it opens the valve *f*, and is added to that already accumulated in the vessel E.

Elasticity of the air increased by condensation.

Having in this manner forced a quantity of air into the vessel E, we can make many experiments in it in this state of condensation. We are chiefly concerned at present, with the effect which this produces on its elasticity. We see this to be greatly increased; for we find more and more force required for introducing every successive barrelful. When the syringe is unscrewed, we see the air rush out with great violence, and every indication of great expanding force. If the syringe be connected with the vessel E, in the same manner as the syringe in No. 17, viz. by interposing a stopcock B between them (see fig. 3.) and if this stopcock have a pipe at its extremity, reaching near to the bottom of the vessel, which is previously half filled with water, we can observe distinctly when the elasticity of the air in the syringe exceeds that of the air in the receiver; for the piston must be pushed down a certain length before the air from the syringe bubbles up through the water, and the piston must be farther down at each successive stroke before this appearance is observed. When the air has thus been accumulated in the receiver, it presses the sides of it outward, and will burst it if not strong enough. It also presses on the surface of the water; and if we now shut the cock, unscrew the syringe, and open the cock again, the air will force the water through the pipe with great velocity, causing it to rise in a beautiful jet. When a metal-receiver is used, the condensation may be pushed to a great length, and the jet will then rise to a great height; which gradually diminishes as the water is expended, and room given to the air to expand itself.

Methods of judging of the condensation, &c.

We judge of the condensation of air in the vessel E, by the number of strokes, and the proportion of the capacity of the syringe to that of the vessel. Suppose the first to be one-tenth of the last; then we know, that after ten strokes the quantity of air in the vessel is doubled, and therefore its density double, and so on after any number of strokes. Let the capacity of the syringe (when the piston is drawn to the top) be a, and that of the vessel be b, and the number of strokes be n, the density of air in the vessel will be $\frac{b+na}{b}$, or $1+\frac{na}{b}$.

But this is on the supposition that the piston accurately fills the barrel, the bottom of the one applying close to that of the other, and that no force is necessary for opening either of the valves; but the first cannot be insured, and the last is very far from being true. In the construction now described, it will require at least one-twentieth part of the ordinary pressure of the air to open the piston valve; therefore the air which gets in will want at least this proportion of its complete elasticity; and there is always a similar part of the elasticity employed in opening the nozzle valve. The condensation therefore is never nearly equal to what is here determined.

It is accurately enough measured by a gage fitted to the instrument. A glass tube GH of a cylindric bore, and close at the end, is screwed into the side of the cap on the mouth of the vessel E. A small drop of mercury is taken into this tube by warming it a little in the hand, which expands the contained air, so that when the open end is dipped into mercury, and the whole allowed to cool, the mercury advances a little into the tube. The tube is furnished with a scale divided into small equal parts, numbered from the close end of the tube. Since this tube communicates with the vessel, it is evident that the condensation will force the mercury along the tube, acting like a piston on the air beyond it, and the air in the tube and vessel will always be of one density. Suppose the number at which the drop stands before the condensation is made to be c, and that it stands at d when the condensation has attained the degree required, the density of the air in the remote end of the gage, and consequently in the vessel, will be $\frac{c}{d}$.

Sometimes there is used any bit of tube close at one end, having a drop of mercury in it, simply laid into the vessel E, and furnished with a scale; but this can only be used with glass vessels, and these are with difficulty made strong enough to resist the pressure arising from great condensation. In such experiments metalline vessels are generally used, fitted with a variety of apparatus for different experiments.

Syringes for great condensations.

It must be observed in this place, that very great condensations require great force, and therefore small syringes. It is therefore convenient to have them of various sizes, and to begin with those of a larger diameter, which operate more quickly; and when the condensation becomes fatiguing, to change the syringe for a smaller.

For this reason, and in general to make the condensing apparatus more convenient, it is proper to have a stop-cock interposed between the syringe and the vessel, or, as it is usually called, the receiver. This consists of a brass pipe, which has a well-ground cock in its middle, and has a hollow screw at one end, which receives the nozzle screw of the syringe, and a solid screw at the other end, which fits the screw of the receiver. (See fig. 3.)

Instances of great condensation.

By these gages, or contrivances similar to them, we have been able to ascertain very great degrees of condensation in the course of some experiments. Dr. Hales found, that when dry wood was put into a strong vessel, which it almost filled, and the remainder was filled with water, the swelling of the wood, occasioned by its imbibition of water, condensed the air of his gage into the thousandth of its original bulk. He found that pease, treated in the same way, generated elastic air, which, pressing on the air in the gage, condensed it into the fifteen-hundreth part of its bulk. This is the greatest condensation that has been ascertained with precision, although in other experiments it has certainly been carried much farther; but the precise degree could not be ascertained.

Some opinions respecting elasticity, &c.

Another important observation is, that in every state of density in which we find it, it retains its perfect fluidity, transmitting all pressures which are applied to it with undiminished force, as appears by the equality constantly observed between the opposing columns of water or other fluid by which it is compressed, and by the facility with which all motions are performed in it in the most compressed states in which we can make observations of this kind. This fact is totally incompatible with the opinion of those who ascribe the elasticity of air to the springy ramified structure of its particles, touching each other like so many pieces of sponge or foot-balls. A collection of such particles might indeed be pervaded by solid bodies with considerable ease, if they were merely touching each other, and not subjected to any external pressure. But the moment such pressure is exerted, and the assemblage squeezed into a smaller space, each presses on its adjoining particles: they are individually compressed, flattened in their touching surfaces, and before the density is doubled they are squeezed into the form of perfect tubes, and compose a mass, which may indeed propagate pressure from one place to another in an imperfect manner, and with great diminution of its intensity, but will no more be fluid than a mass of soft clay.

Consequences of the air's elasticity.

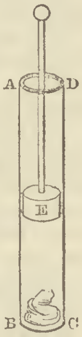
We have seen the air is heavy and compressible, and might now proceed to deduce in order the explanation of the appearances consequent on each of these properties. But, as has been already observed, the elasticity of air modifies the effects of its gravity so remarkably, that they would be imperfectly understood if both qualities were not combined in our consideration of either. At any rate, some farther consequences of its elasticity must be considered, before we understand the means of varying at pleasure the effects of its gravity.

Its great expansibility proved by experiment.

Since air is heavy, the lower strata of a mass of air must support the upper; and, being compressible, they must be condensed by their weight. In this state of compression the elasticity of the lower strata of air acts in opposition to the weight of the incumbent air, and balances it. There is no reason which should make us suppose that its expanding force belongs to it only when in such a state of compression. It is more probable that, if we could free it from this pressure, the air would expand itself into still greater bulk. This is most distinctly seen in the following experiment.

Into the cylindric jar ABCD, (fig. 11,) which has a small hole in its bottom, and is furnished with an air-tight piston E, put a small flaccid bladder, having its mouth tied tight with a string. Having pushed the piston near to the bottom, and noticed the state of the bladder, stop up the hole in the bottom of the jar with the finger, and draw up the piston, which will require a considerable force. You will observe the bladder swell out, as if air had been blown into it; and it will again collapse on allowing the piston to descend. Nothing can be more unexceptionable than the conclusion from this experiment, that ordinary air is in a state of compression, and that its elasticity is not limited to this state. The bladder being flaccid, shews that the included air is in the same state with the air which surrounds it; and the same must be affirmed of it while it swells but still remains flaccid. We must conclude that the whole air within the vessel expands, and continues to fill it, when its capacity has been enlarged. And since this is observed to go on as long as we give it more room, we conclude, that by such experiments we have not yet given it so much room as it can occupy.

Fig. 11.

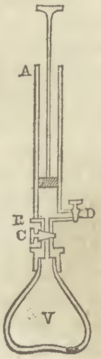


Attempts to discover the limits of this expansion.

It was a natural object of curiosity to discover the limits of this expansion; to know what was the natural unconstrained bulk of a quantity of air, beyond which it would not expand though all external compressing force were removed. Accordingly philosophers constructed instruments for *rarefying* the air. The common water-pump had been long familiar, and appeared very proper for this purpose. The most obvious is the following.

Let the barrel of the syringe AB communicate with the vessel V, with a stopcock C between them. Let it communicate with the external air by another orifice D, in any convenient situation, also furnished with a stopcock. Let this syringe have a piston very accurately fitted to it so as to touch the bottom all over when pushed down, and have no vacancy about the sides.

Fig. 12.



Now, suppose the piston at the bottom, the cock C open, and the cock D shut, draw the piston to the top. The air which filled the vessel V will expand so as to fill both that vessel and the barrel AB; and, as no reason can be given to the contrary, we must suppose that the air will be uniformly diffused through both. Calling V and B the capacity of the vessel and barrel, it is plain that the bulk of the air will now be V+B; and since the quantity of matter remains the same, and the density of a fluid is as its quantity of matter directly and its bulk inversely, the density of the expanded air will be $\frac{V}{V+B}$, the density of common air being 1; for V+B; V=1; $\frac{V}{V+B}$.

The piston requires force to raise it, and it is raised in opposition to the pressure of the incumbent atmosphere; for this had formerly been balanced by the elasticity of the common air; and we conclude from the fact, *that force is required to raise the piston*, that the elasticity of the expanded air is less than that of air in its ordinary state; and an accurate observation of the force necessary to raise it would shew how much the elasticity is diminished. When therefore the piston is let go, it will descend as long as the pressure of the atmosphere exceeds the elasticity of the air in the barrel; that is, till the air in the barrel is in a state of ordinary density. To put it further down will require force, because the air must be compressed in the barrel; but if we open the cock D, the air will be expelled through it, and the piston will reach the bottom.

Now shut the *discharging cock* D, and open the cock C, and draw the piston. The air which occupied the space V, with the density $\frac{V}{V+B}$, will now occupy the space V+B, if it expands so far. To have its density D, say, As its present bulk V+B is to its former bulk V, so its former density $\frac{V}{V+B}$ to its new density; which will therefore be $\frac{V+V}{\overline{V+B+V+B}}$, or $\overline{\frac{V}{V+B}}\Big|^{2}$.

It is evident, that if the air continues to expand, the density of the air in the vessel after the third drawing up of the piston will be $\overline{\frac{V}{V+B}}\Big|^{2}$, after the fourth it will be $\overline{\frac{V}{V+B}}\Big|^{4}$, and after any number of strokes n will be $\overline{\frac{V}{V+B}}\Big|^{n}$. Thus, if the vessel is four times as large as the barrel, the density after the fifth stroke will be $\frac{1024}{3125}$, nearly $\frac{1}{3}$ of its ordinary density.

On the other hand, the number n of strokes necessary for reducing air to the density D is $\frac{\log D}{\log V-\log (V+B)}$.

Some inconveniences of this instrument.

Thus we see that this instrument can never abstract the whole air in consequence of its expansion, but only rarefy it continually as long as it continues to expand; nay, there is a limit beyond which the rarefaction cannot go. When the piston has reached the bottom, there remains a small space between it and the cock C filled with common air. When the piston is drawn up, this small quantity of air expands, and also a similar quantity in the neck of the other cock; and no air will come out of the receiver V till the expanded air in the barrel is or a smaller density than the air in the receiver. This circumstance evidently directs us to make these two spaces as small as possible, or by some contrivance to fill them up altogether. Perhaps this may be done effectually in the following manner.

Fig. 13.

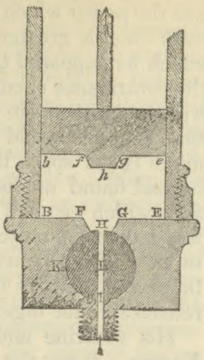


Fig. 14.

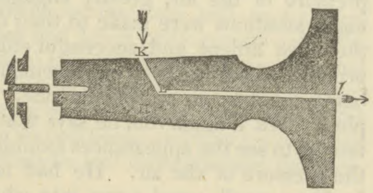


Let BE represent the bottom of the barrel, and let the circle HKI be the section of the key of the cock, of a large diameter, and place it as near to the barrel as can be. Let this communicate with the barrel by means of a hole FG widening upwards, as the frustum of a hollow obtuse cone. Let the bottom of the piston *b f h g e* be shaped so as to fit the bottom of the barrel and this hole exactly. Let the cock be pierced with two holes. One of them, HI, passes perpendicularly through its axis, and forms the communication between the receiver and barrel. The other hole, KL, has one extremity K on the same circumference with H, so that when the key is turned a fourth part round, K will come into the place of H: but this hole is pierced obliquely into the key, and thus keeps clear of the hole HI. It goes no further than the axis, where it communicates with a hole bored along the axis and terminating at its extremity. This hole forms the communication with the external air, and serves for discharging the air in the barrel. (A side view of the key is seen in fig. 14.) Fig. 13 shows the position of the cock while the piston is moving upwards, and fig. 14 shows its position while the piston is moving downwards. When the piston has reached the bottom, the conical piece *f h g* of the piston, which may be of firm leather, fills the hole FHG, and therefore completely expels the air from the barrel. The canal KL *l* of the cock contains air of the common density; but this is turned aside into the position KL (fig. 13), while the piston is still touching the cock. It cannot extend into the barrel during the ascent of the piston. In place of it the perforation HLI comes under the piston, filled with air that had been turned aside with it when the piston was at the top of the barrel, and therefore of the same density with the air of the receiver. It appears therefore that there is no limit to the rarefaction as long as the air will expand.

This instrument is called an Exhausting Syringe. It is more generally made in another form, which is much less expensive, and more convenient in its use. Instead of being furnished with *cocks* for establishing the communications and shutting them, as is necessary, it has *valves* like those of the condensing syringe, but opening in the opposite direction from those in fig. 10.

This syringe is evidently more easy in its use, requiring no attention to the cocks to open and shut them at the proper times. On this account this construction of an exhausting syringe is much more generally used.

But it is greatly inferior to the syringe with cocks, with respect to its power of rarefaction. It is evident that no air will come out of the receiver unless its elasticity *exceed* that of the air in the barrel by a difference able to lift up the valve fig. 10. A piece of waxed silk tied across this hole can hardly be made tight and certain of clapping to the hole without some small straining, which must therefore be overcome. It must be very gentle indeed not to require a force equal to the weight of two inches of water, and this is equal to about the 200th part of the whole elasticity of the ordinary air; and therefore this syringe, for this reason alone, cannot rarefy air above 200 times, even though air were capable of an indefinite expansion. In like manner the valve in the piston cannot be raised without a similar prevalence of the elasticity of the air in the barrel above the weight of the atmosphere. These causes united, make it difficult to rarefy the air more than 100 times, and very few such syringes will rarefy it more than 50 times; whereas the syringe with cocks, when new and in good order, will rarefy it 1000 times.

But, on the other hand, syringes with cocks are much more expensive, especially when furnished with apparatus for opening and shutting the cocks. They are more difficult to make equally tight, and (which is the greatest objection) do not remain long in good order. The cocks, by so frequently opening and shutting, grow loose, and allow the air to escape. No method has been found of preventing this. They must be ground tight by means of emery or other cutting powders. Some of these unavoidably stick in the metal, and continue to wear it down. For this reason philosophers, and the makers of philosophical instruments, have turned their chief attention to the improvement of the syringe with valves.

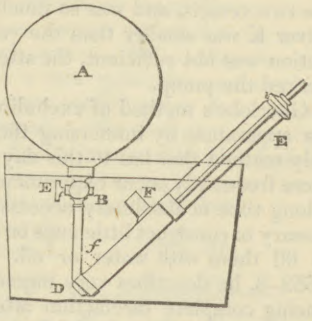
OF THE AIR-PUMP.

Invention of the air-pump by Guericke.

An Air-Pump is nothing but an exhausting syringe accommodated to a variety of experiments. It was first invented by Otto Guericke, a gentleman of Magdeburgh in Germany, about the year 1654. We trust that it will not be unacceptable to our readers to see this instrument in its first form, and to trace it through its successive steps to its present state of improvement.

Guericke gave a minute description of all his pneumatic apparatus to Gaspar Schottus, professor of mathematics at Wirtemberg, who immediately published it with the author's consent, with an account of some of his performances, first in 1657, in his *Mechanica Hydraulico-pneumatica;* and then in his *Technica Curiosa*, in 1664.

Fig. 16.



Construction of his pump.

Otto Guericke's air-pump consists of a glass receiver A of a form nearly spherical, fitted up with a brass cap and cock B. The nozzle of the cap was fixed to a syringe DE, also of brass, bent at D into half a right angle. This had a valve at D, opening from the receiver into the syringe, and shutting when pressed in the opposite direction. In the upper side of the syringe there is another valve F, opening from the syringe into the external air, and shutting when pressed inwards. The piston had no valve. The syringe, the cock B, and the joint of the tube, were immersed in a cistern filled with water. From this description, it is easy to understand the operation of the instrument. When the piston was drawn up from the bottom of the syringe, the valve F was kept shut by the pressure of the external air, and the valve D opened by the elasticity of the air in the receiver. When it was pushed down again, the valve D immediately shut by the superior elasticity of the air in the syringe; and when this was sufficiently compressed, it opened the valve F, and was discharged. It was immersed in water, that no air might find its way through the joints or cocks.

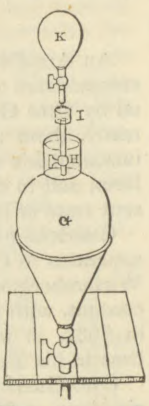
Its imperfections.

It would seem that this machine was not very perfect; for Guericke says, that it took several hours to produce an evacuation of a moderate-sized vessel; but he says, that when it was in good order, the rarefaction was so great, that when the cock was opened, and water admitted, it filled the receiver so as sometimes to leave no more than the bulk of a pea filled with air. This is a little surprising; for if the valve F be placed as far from the bottom of the syringe as in Schottus' figure,[1] it would appear that the rarefaction could not be greater than what must arise from the air in DF, expanding till it filled the whole syringe: because, as soon as the piston in its descent passes F, it can discharge no more air, but must compress it between F and the bottom, to be expanded again when the piston is drawn up. It is probable that the piston was not very tight, but that on pressing it down, it allowed the air to pass it; and the water in which the whole was immersed prevented the return of the air when it was drawn up again; and this accounts for the great time necessary for producing the desired rarefaction.

His improvement of it.

Guericke added a part to the machine, which saved his numerous visitants the trouble of hours' attendance, before they could see the curious experiments with rarefied air. He made a large copper vessel G (fig. 17.), having a pipe and cock below, which passed through the floor of the chamber into an under apartment, where it was joined to the syringe immersed in the cistern of water, and worked by a lever. The upper part of the vessel terminated in a pipe, furnished with a stopcock H, surrounded with a small brim to hold water for preventing the ingress of air. On the top was another cap I, also filled with water, to protect the junction of the pipes with the receiver K. This great vessel was always kept exhausted, and workmen attended below. When experiments were to be performed in the receiver K, it was set on the top of the great vessel, and the cock H was opened. The air in K immediately diffused itself equally between the two vessels, and was so much more rarefied as the receiver K was smaller than the vessel G. When this rarefaction was not sufficient, the attendants below immediately worked the pump.

Fig. 17.



Guericke's method of excluding air from all the joints of his apparatus, by immersing these joints in water, is the only method that has to this day been found effectual; and there frequently occur experiments where this exclusion for a long time is absolutely necessary. In such cases it is necessary to construct little cups or cisterns at every joint, and to fill them with water or oil. In a letter to Schottus, 1662–3, he describes very ingenious contrivances for producing complete rarefaction after the elasticity of the remaining air has been so far diminished that it is not able to open the valves. He opens the exhausting valves by a plug, which is pushed in by the hand; and the discharging valve is opened by a small pump placed on its outside, so that it opens into a void instead of opening against the pressure of the atmosphere.[2] These contrivances have been lately added to air-pumps by Haas and Hurter as new inventions.

Merits of Guericke.

It must be acknowledged, that the application of the pump or syringe to the exhaustion of air was a very obvious thought on the principle exhibited in fig. 3; and in this way it was also employed by Guericke, who first filled the receiver with water, and then applied the syringe. But this was by no means either his object or his principle. His object was not solely to procure a vessel void of air, but to exhaust the air which was already in it; and his principle was the power which he suspected to be in air of expanding itself into a greater space when the force was removed which he supposed to compress it. He expressly says,[3] that the contrivance occurred to him accidentally when occupied with experiments in the Toricellian tube, in which he found that the air would really expand, and completely fill a much larger space than what it usually occupied, and that he had found no limits to the expansion, evincing this by facts which we shall perfectly understand by and bye. This was a doctrine quite new, and required a philosophical mind to view it in a general and systematic manner; and it must be owned, that his manner of treating the subject is equally remarkable for ingenuity and for modesty.

Progress of experimental philosophy.

His doctrine and his machine were soon spread over Europe. It was the age of literary ardour and philosophical curiosity; and it is most pleasant to us, who, standing on the shoulders of our predecessors, can see far around us, to observe the eagerness with which every new, and to us frivolous, experiment was repeated and canvassed.

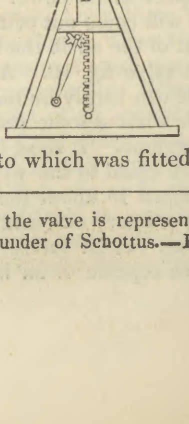
Ardour of Mr. Boyle.

About this time the foundations of the Royal Society of London were laid. Mr. Boyle, Mr. Wren, Lord Brounker, Dr. Wallis, and others, held meetings at Oxford, in which were received accounts of whatever was doing in the study of nature; and many experiments were exhibited. The researches of Galileo, Toricelli, and Pascal, concerning the pressure of the air, greatly engaged their attention, and many additions were made to their discoveries. Mr. Boyle, the most ardent and successful studier of nature, had the principal share in these improvements, his inquisitive mind being aided by an opulent fortune. In a letter to his nephew Lord Dungarvon, he says that he had made many attempts to see the appearances exhibited by bodies freed from the pressure of the air. He had made Toricellian tubes, having a small vessel a-top, into which he put some bodies before filling the tubes with mercury; so that when the tube was set upright, and the mercury run out, the bodies were *in vacuo*. He had also abstracted the water from a vessel by a small pump, by means of its weight, in the manner shewn in fig. 3, having previously put bodies into the vessel along with the water. But all these ways were very troublesome and imperfect. He was delighted when he learned from Schottus' first publication, that Guericke had effected this by the expansive power of the air; and immediately set about constructing a machine from his own ideas, no description of Guericke's being then published.

His air-pump.

It consisted of a receiver A, (fig. 18.) furnished with a stopcock B, and syringe CD placed in a vertical position below the receiver. Its valve C was in its bottom, close adjoining to the entry of the pipe of communication; and the hole by which the air issued was farther secured by a plug which could be removed. The piston was moved by a wheel and rack-work. The receiver of Guericke's pump was but ill adapted for any considerable variety of experiments; and accordingly very few were made in it. Mr. Boyle's receiver had a large opening EF, with a strong glass margin. To this was fitted a strong brass cap, pierced with a hole G in its middle, to which was fitted a

Fig. 18.



---

[1] In Guericke's own account of these discoveries, published in 1672, eight years after the *Technica Curiosa*, the valve is represented at *f*, close to the bottom of the syringe; hence it would appear that the representing it in the middle at F was a blunder of Schottus.—Ed.

[2] See Schotti *Technica Curiosa*, p. 68—70.

[3] *Tractatus de Experimentis Magdeburgicis, et Epistolæ ad Schottum.*

plug ground into it, and shaped like the key of a cock. The extremity of this key was furnished with a screw, to which could be affixed a hook, or a variety of pieces for supporting what was to be examined in the receiver, or for producing various motions within it, without admitting the air. This was farther guarded against by means of oil poured round the key, where it was retained by the hollow cup-like form of the cover. With all these precautions, however, Mr. Boyle ingenuously confesses, that it was but seldom, and with great difficulty, that he could produce an extreme degree of rarefaction; and it appears by Guericke's letter to Schottus that in this respect the Magdeburgh machine had the advantage. But most of Boyle's very interesting experiments did not require this extreme rarefaction; and the variety of them, and their philosophic importance, compensated for this defect, and soon eclipsed the fame of the inventor to such a degree, that the state of air in the receiver was generally denominated the *vacuum Boyleanum*, and the air-pump was called *machina Boyleana*.

His contrivances to make air-vessels tight.

Mr. Boyle found, that to make a vessel air-tight, it was sufficient to place a piece of wet or oiled leather on its brim, and to lay a flat plate of metal on this. The pressure of the external air squeezed the two solid bodies so hard together, that the soft leather effectually excluded it. This enabled him to render the whole machine incomparably more convenient for a variety of experiments. He caused the conduit-pipe to terminate in a flat plate which he covered with leather, and on this he set the glass ball or receiver, which had both its upper and lower brim ground flat. He covered the upper orifice in like manner with a piece of oiled leather and a flat plate, having cocks and a variety of other perforations and contrivances suited to his purposes. This he found infinitely more expeditious, and also tighter than the clammy cements which he had formerly used for securing the joints.

Dr Hooke's improvement of Boyle's air-pump.

Fig. 19.

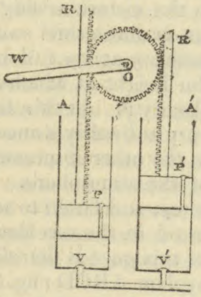


Fig. 20.

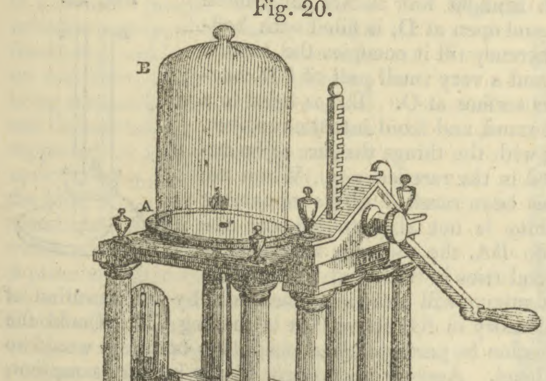
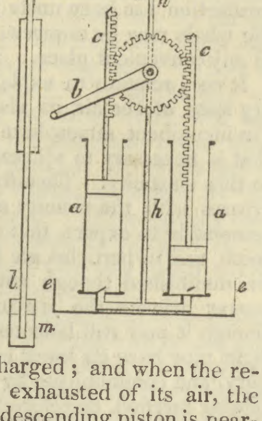


He was now assisted by Dr. Hooke, the most ingenious and inventive mechanic that the world has ever seen. This person made a great improvement on the air-pump, by applying two syringes AA, (fig. 19), whose pistons P and P′ are both worked by one wheel, O pitching in the racks or piston rods R and R′, the pistons being thus raised and depressed alternately by turning the winch W backwards and forwards. In the bottom of each of the barrels there is an opening communicating with the receiver or bell glass B, placed on the plate A, (fig. 20). Over these openings valves of oiled silk are so placed as to admit of the passage of the air from the receiver to the syringe or barrel, but to oppose its passage from the barrel to the receiver. Now, suppose either of the pistons to be at the bottom of its barrel, it is obvious, that on drawing it up a vacuum will be found in the lower portion of the barrel, until the air in the receiver, by its elastic force, opening the valve V or V′, rushes in, distributing itself equally betwixt the barrel and receiver, but as the pistons are furnished with valves P and P′ similar to and opening in the same direction as VV′; on the descent of the piston the air which occupies the space betwixt the piston and bottom of the barrel being prevented from returning to the receiver by the valve V or V′, opens the valve in the piston and escapes into the apartment, with the air of which the piston valve communicates. This evidently doubled the expedition of the pump's operation; but it also greatly diminished the labour of pumping; for it must be observed, that the piston P must be drawn up against the pressure of the external air, and when the rarefaction is nearly perfect, this requires a force of nearly fifteen pounds for every inch of the area of the piston. Now when one piston P is at the bottom of the barrel, the other P′ is at the top of the barrel, and the air below P′ is equally rare with that in the receiver. Therefore the pressure of the external air on the piston P′ is *nearly* equal to that on the piston P. Both, therefore, are acting in opposite directions on the wheel which gave them motion; and the force necessary for raising P is only the difference between the elasticity of the air in the barrel P, and that of the air in the barrel P′. This is very small in the beginning of the stroke, but gradually increases as the piston P′ descends, and becomes equal to the whole excess of the air's pressure above the elasticity of the remaining air of the receiver, when the air at P of the natural density begins to open the piston valves. An accurate attention to the circumstances will show us that the force requisite for working the pump is greatest at first, and gradually diminishes as the rarefaction advances; and when this is nearly complete, hardly any more force is required than what is necessary for overcoming the friction of the pistons, except during the discharge of the air at the end of each stroke. This is therefore the form of the air-pump which is most generally used over all Europe; though in the various modifications some traces of national prepossession remain. We shall give a description of Boyle's air-pump as finally improved by Hawkesbee, which, with some small accommodations to particular views, continued for many years the most approved form.

Hawkesbee's improvements

Fig. 21.



It consists of two brass barrels *a a*, (fig. 21.) twelve inches high, and two wide. The pistons are raised and depressed by turning the winch *b*. This is fastened to an axis passing through a strong toothed wheel, which lays hold of the teeth of the racks *c c*. Then the one is raised while the other is depressed; by which means the valves, which are made of limber bladder, fixed in the upper part of each piston, as well as in the openings into the bottom of the barrels, perform their office of discharging the air from the barrels, and admitting into them the air from the receiver to be afterwards discharged; and when the receiver comes to be pretty well exhausted of its air, the pressure of the atmosphere in the descending piston is nearly so great, that the power required to raise the other is little more than is necessary for overcoming the friction of the piston, which renders this pump preferable to all others, which require more force to work them as the rarefaction of the air in the receiver advances.

The barrels are set in a brass dish about two inches deep, filled with water or oil to prevent the insinuation of air. The barrels are screwed tight down by the nuts *e e*, which force the frontispiece *f f* down on them, through which the two pillars *g g* pass; for the sake of distinctness these are omitted in the figure.

From between the barrels rises a slender brass pipe *h h*, communicating with each by a perforation in the transverse piece of brass on which they stand. The upper end of this pipe communicates with another perforated piece of brass, which screws on underneath the plate *i i*, of ten inches diameter, and surrounded with a brass rim to prevent the shedding of water used in some experiments. This piece of brass has three branches. 1st, An horizontal one communicating with the conduit pipe *h h*. 2d, An upright one, screwed into the middle of the pump plate, and terminating in a small pipe *k*, rising about an inch above it. 3d, A perpendicular one, looking downwards in the continuation of the pipe *k*, and having a hollow screw in its end receiving the brass cap of the gage-pipe *l l*, which is of glass, thirty-four inches long, and immersed in a glass cistern *m* filled with mercury. This is covered a-top with a cork float, carrying the weight of a light wooden scale divided into inches, which are numbered from the surface of the mercury in the cistern. This scale will therefore rise and fall with the mercury in the cistern, and indicate the true elevation of that in the tube.

There is a stop-cock immediately above the insertion of the gage-pipe, by which its communication may be cut off. There is another at *n*, by which a communication is opened with the external air, for allowing its readmission; and there is sometimes another immediately within the insertion of the conduit-pipe for cutting off the communication between the receiver and the pump. This is particularly useful when the rarefaction is to be continued long, as there are by these means fewer chances of the insinuation of air by the many joints.

The receivers are made tight by simply setting them on the pump-plate, with a piece of wet or oiled leather between; and the receivers, which are open a-top, have a brass cover set on them in the same manner. In these covers there are various perforations and contrivances for various purposes. The one in the figure has a slip wire passing through a collar of oiled leather, having a hook or a screw in its lower end, for hanging any thing on, or producing a variety of motions.

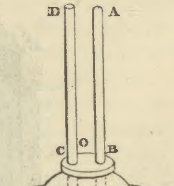
Sometimes the receivers are set on another plate, which has a pipe screwed into its middle, furnished with a stop-cock and a screw, which fits the middle pipe *k*. When the rarefaction has been made in it, the cock is shut, and then the whole may be unscrewed from the pump, and removed to any convenient place. This is called a *transporter plate.*

It only remains to explain the gage *ll*. In the ordinary state of the air, its elasticity balances the pressure of the incumbent atmosphere. We find this from the force that is necessary to squeeze it into less bulk in opposition to this elasticity. Therefore the elasticity of the air increases with the vicinity of its particles. It is therefore reasonable to expect, that when we allow it to occupy more room, and its particles are further asunder, its elasticity will be diminished though not annihilated; that is, it will no longer balance the WHOLE pressure of the atmosphere, though it may still balance part of it. If therefore an upright pipe have its lower end immersed in a vessel of mercury, and communicate by its upper end with a vessel containing rarefied, therefore less elastic air, we should expect that the pressure of the air will prevail, and force the mercury into the tube, and cause it to rise to such a height that the weight of the mercury, joined to the elasticity of the rarefied air acting on its upper surface, shall be exactly equal to the whole pressure of the atmosphere. The height of the mercury is the exact measure of that part of the whole pressure which is not balanced by the elasticity of the rarefied air, and its deficiency from the height of the mercury in the Toricellian tube is the exact measure of this remaining elasticity.

It is evident, therefore, that the pipe will be a scale of the elasticity of the remaining air, and will indicate in some sort the degree of rarefaction; for there must be some analogy between the density of the air and its elasticity; and we have no reason to imagine that they do not increase and diminish together, although we may be ignorant of the law, that is, of the change of elasticity corresponding to a known change of density. This is to be discovered by experiment; and the air-pump itself furnishes us with the best experiments for this purpose. After rarefying till the mercury in the gage has attained half the height of that in the Toricellian tube, shut the communication with the barrels and gage, and admit the water into the receiver. It will go in till all is again in equilibrio with the pressure of the atmosphere; that is, till the air in the receiver has collapsed into its natural bulk. This we can accurately measure, and compare with the whole capacity of the receiver; and thus obtain the precise degree of rarefaction corresponding to half the natural elasticity. We can do the same thing with the elasticity reduced to one-third, one-fourth, &c. and thus discover the whole law.

This gage must be considered as one of the most ingenious and convenient parts of Hawkesbee's pump; and it is well disposed, being in a situation protected against accidents; but it necessarily increases greatly the size of the machine, and cannot be applied to the table-pump represented in fig. 20. When it is wanted here, a small plate is added behind, or between the barrels and receiver; and on this is set a small tubulated (as it is termed) receiver, covering a common weather-glass tube. This receiver being rarefied along with the other, the pressure on the mercury in the cistern arising from the elasticity of the remaining air, is diminished so as to be no longer able to support the mercury at its full height; and it therefore descends till the height at which it stands puts it in equilibrio with the elasticity. In this form, therefore, the height of the mercury is directly a measure of the remaining elasticity; while in the other it measures the remaining unbalanced pressure of the atmosphere. But this gage is extremely cumbersome, and liable to accidents. We are seldom much interested in the rarefaction till it is great; a contracted form of this gage is therefore very useful, and was early used. A syphon ABCD (fig. 22.) each branch of which is about four inches long, close at A and open at D, is filled with boiling mercury till it occupies the branch AB, and a very small part of CD, having its surface at O. This is fixed to a small stand, and fixed into the receiver, along with the things that are to be exhibited in the rarefied air. When the air has been rarefied till its remaining elasticity is not able to support the column BA, the mercury descends in AB, and rises in CD, and the remaining elasticity will always be measured by the elevation of the mercury in AB above that in the leg CD. Could the exhaustion be perfected, the surfaces in both legs would be on a level. Another gage might be put into the same foot, having a small bubble of air at A. This would move from the beginning of the rarefaction; but our ignorance of the analogy between the density and elasticity hinders us from using it as a measure of either.

Fig. 22.



A complete exhaustion not effected by the air-pump.

It is enough for our present purpose to observe, that the barometer gage is a perfect indication and measure of the performance of an air-pump, and that a pump is, *cæteris paribus*, so much the more perfect, as it is able to raise the mercury higher in the gage. It is in this way that we discover that none can produce a complete exhaustion, and that their operation is only a very great rarefaction: for none can raise the mercury to that height at which it stands in the Toricellian tube, well purged of air. Few pumps will bring it within one-tenth of an inch. Hawkesbee's, fitted up according to his instructions, will seldom bring it within one-fifth. Pumps with cocks, when constructed according to the principles mentioned when speaking of the exhausting syringe, and new and in fine order, will in favourable circumstances bring it within one-fortieth. None with valves fitted up with wet leather, or when water or volatile fluids are allowed access into any part, will bring it nearer than one-fifth. Nay, a pump of the best kind, and in the finest order, will have its rarefying power reduced to the lowest standard, as measured by this gage, if we put into the receiver the tenth part of a square inch of white sheep-skin, fresh from the shops, or of any substance equally damp. This is a discovery made by means of the improved air-pump, and leads to very extensive and important consequences in general physics, some of which will be treated of under this article; and the observation is made thus early, that our readers may better understand the improvements which have been made on this celebrated machine.

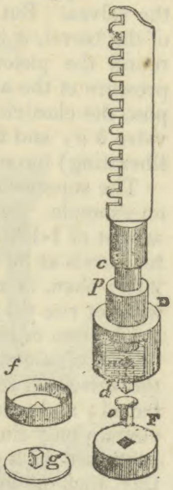
Various improvements of this machine.

It would require a volume to describe all the changes which have been made on it. An instrument of such multifarious use, and in the hands of curious men, each diving into the secrets of nature in his favourite line, must have received many alterations and real improvements in many particular respects. But these are beside our present purpose; which is to consider it merely as a machine for rarefying elastic or expansive fluids. We must therefore confine ourselves to this view of it; and shall carefully state to our readers every improvement founded on principle, and on pneumatical laws. All who used it perceived the limit set to the rarefaction by the resistance of the valves, and tried to perfect the construction of the cocks. The Abbé Nollet and s'Gravesande, two of the most eminent experimental philosophers in Europe, were the most successful.

s'Gravesande's improvement.

Mr. s'Gravesande justly preferred Hooke's plan of a double pump, and contrived an apparatus for turning the cocks by the motion of the pump's handle. This is far from either being simple or easy in working; and occasions great jerks and concussions in the whole machine. This, however, is not necessarily connected with the truly pneumatical improvement. His piston has no valve, and the rod is connected with it by a stirrup D (fig. 23), as in a common pump. The rod has a cylindric part *c p*, which passes through the stirrup, and has a stiff motion in it up and down of about half an inch; being stopped by the shoulder *c* above and the nut below. The round plate supported by this stirrup has a short square tube *n d*, which fits tight into the hole of a piece of cork F. The round plate E has a square shank *g*, which goes into the square tube *n d* A piece of thin leather *f*, soaked in oil, is put between the cork and the plate E, and another between the cork and the plate which forms the sole of the stirrup. All these pieces are screwed together to form the piston by the nail *e*, whose flat head covers the hole *n*. Suppose, therefore, the piston touching the bottom of the barrel, and the winch turning to raise it again, the friction of the piston on the barrel keeps it in its place, and the rod is drawn up through the stirrup D. Thus the wheel has liberty to turn about an inch; and this is sufficient for turning the cock, so as to cut off the communication with the external air, and to open the communication with the receiver. This being done, and the motion of the winch continued, the piston is raised to the top of the barrel. When the winch is turned in the opposite direction, the piston remains fixed till the cock is turned, so as to shut the communication with the receiver, and open that with the external air.

Fig. 23.



This is a pretty contrivance, and does not at first appear necessary; because the cocks might be made to turn at the beginning and end of the stroke without it. But this is just possible; and the smallest error of adjustment, or wearing of the apparatus, will cause them to be open at improper times. Besides, the cocks are not turned in an instant, and are improperly open during some very small time; but this contrivance completely obviates the difficulty.

The cock is precisely similar to that formerly described, having one perforation diametrically through it, and another entering at right angles to this, and after reaching the centre, it passes along the axis of the cock, and comes out to the open air.

Its inconveniences remedied.

It is evident, that by this construction of the cock, the ingenious improvement of Dr. Hooke, by which the pressure of the atmosphere on one piston is made to balance, in great part, the pressure on the other, is given up: for, whenever the communication with the air is opened, it rushes in, and immediately balances the pressure on the upper side of the piston in this barrel; so that the whole pressure in the other must be overcome by the person working the pump. Gravesande, aware of this, put a valve on the orifice of the cock; that is, tied a slip of wet bladder or oiled leather across it; and now the piston is pressed down, as long as the air in the barrel is rarer than the outward air, in the same manner as when the valve is in the piston itself.

This is all that is necessary to be described in Mr. s'Gravesande's air pump. Its performance is highly extolled by him, as far exceeding his former pumps with valves. The same preference was given to it by his successor Muschenbrock. But, while they both prepared the pistons and valves and leathers of the pump, by steeping them in oil, and then in a mixture of water and spirits of wine, we are certain that no just estimate could be made of its performance. For with this preparation it could not bring the gage within one-fifth of an inch of the barometer. We even see other limits to its rarefaction: from its construction, it is plain that a very considerable space is left between the piston and cock, not less than an inch, from which the air is never expelled; and if this be made extremely small, it is plain that the pump must be worked very slow, otherwise there will not be time for the air to diffuse itself from the receiver into the barrel, especially towards the end, when the expelling force, viz. the elasticity of the remaining air, is very small. There is also the same limit to the rarefaction, as in Hooke's or Hawkesbee's pump, opposed by the valve, which will not open till the air below the piston is considerably denser than the external air; and this pump soon lost any advantages it possessed when fresh from the workman's hands, by the cock's growing loose and admitting air. It is surprising that Gravesande omitted Hawkesbee's security against this, by placing the barrels in a dish filled with oil; which would effectually have prevented this inconvenience.

Advantage of short barrels.

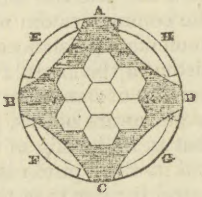
We must not omit a seemingly paradoxical observation of s'Gravesande, that in a pump constructed with valves, and worked with a determined uniform velocity, the required degree of rarefaction is sooner produced by short barrels than by long ones. It would require too much time to give a general demonstration of this, but it will easily be seen by an example. Suppose the long barrel to have equal capacity with the receiver, then at the end of the first stroke the air in the receiver will have one-half its natural density. Now, let the short barrrels have half this capacity: at the end of the first stroke the density of the air in the receiver is two-thirds, and at the end of the second stroke it is four-ninths, which is less than one-half, and the two strokes of the short barrel are supposed to be made in the same time with one of longest, &c.

The valve pump improved by Smeaton

Hawkesbee's pump maintained its pre-eminence without rival in Britain, till about the year 1750, when it engaged the attention of Mr. John Smeaton. He was then a maker of philosophical instruments, and made many attempts to perfect the pumps with cocks, but found, that whatever perfection he could bring them to, he could not enable them to preserve it; and he never would sell one of this construction. He therefore attached himself solely to the valve pumps.

The first thing was to diminish the resistance to the entry of the air from the receiver into the barrels; and this he rendered almost nothing, by enlarging the surface on which this feebly elastic air was to press. Instead of making these valves to open by its pressure on a circle of one-twentieth of an inch in diameter, he made the valve-hole one inch in diameter, enlarging the surface 400 times; and, to prevent this piece of thin leather from being burst by the great pressure on it, when the piston in its descent was approaching the bottom of the barrel, he supported it by a delicate but strong grating, dividing the valve-hole like the section of a honey-comb, as represented in fig. 24; and the ribs of this grating are seen edgewise in fig. 25, at *a b c*.

Fig. 24.



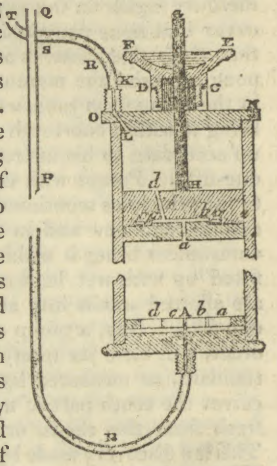
The valve was a piece of thin membrane or oiled silk, gently strained over the mouth of the valve-hole, and tied on by a fine silk thread wound round it in the same manner that the narrow slips had been tied on formerly. This done, he cut with a pointed knife the leather round the edge, nearly four quadrantal arcs, leaving a small tongue between each, as in fig. 24. The strained valve immediately shrinks inwards, as represented by the shaded parts; and the strain by which it is kept down is now greatly diminished, taking place only at the corners. The gratings being reduced nearly to an edge (but not quite, lest they should cut), there is very little pressure to produce adhesion by the clammy oil. Thus it appears, that a very small elasticity of the air in the receiver will be sufficient to raise the valve; and Mr. Smeaton found, that when it was not able to do this at first, when only about $\frac{1}{600}$ of the natural elasticity, it would do it after keeping the piston up eight or ten seconds, the air having been all the while undermining the valve, and gradually detaching it from the grating.

Unfortunately he could not follow this method with the piston valve. There was not room round the rod for such an expanded valve; and it would have obliged him to have a great space below the valve, from which he could not expel the air by the descent of the piston. His ingenuity hit on a way of increasing the expelling force through the common valve. He inclosed the rod of the piston in a collar of leather D C (fig. 25,) through which it moved freely without allowing any air to get past its sides. For greater security, the collar of leather was contained in a box terminating in a cup filled with oil. As this makes a material change in the principle of construction of the air-pump, and indeed of pneumatic engines in general, and as it has been adopted in all the subsequent attempts to improve them, it merits a particular consideration.

Structure of his piston.

The piston itself consists of two pieces of brass fastened by screws from below. The uppermost, which is of one solid piece with the rod GH (fig. 25), is of a diameter somewhat less than the barrel; so that when they are screwed together, a piece of leather soaked in a mixture of boiled oil and tallow, is put between them; and when the piston is thrust into the barrel from above, the leather comes up around the side of the piston, and fills the barrel, making the piston perfectly air-tight. The lower half of the piston projects upwards into the upper, which has a hollow *g b c d* to receive it. There is a small hole through the lower half at *a* to admit the air; and a hole *c d* in the upper half to let it through, and there is a slip of oiled silk strained across the hole *a* by way of valve, and there is room enough left at *b c* for this valve to rise a little when pressed from below. The rod GH passes through the piece of brass which forms the top of the barrel so as to move freely, but without any sensible shake: this top is formed into a hollow box, consisting of two pieces ECDF and CNOD, which screw together at CD. This box is filled with rings of oiled leather exactly fitted to its diameter, each having a hole in it for the rod to pass through. When the piece ECDF is screwed down, it compresses the leathers; squeezing them to the rod, so that no air can pass between them; and, to secure us against all ingress of air, the upper part is formed into a cup EF, which is kept filled with oil.

Fig. 25.



The top of the barrel is also pierced with a hole LK, which rises above the flat surface NO, and has a slip of oiled silk tied over it to act as a valve; opening when pressed from below, but shutting when pressed from above.

The communication between the barrel and receiver is made by means of the pipe ABPQ; and there goes from the hole K in the top of the barrel a pipe KRST, which either communicates with the open air or with the receiver, by means of the cock at its extremity T. The conduit pipe ABPQ has also a cock at Q, by which it is made to communicate either with the receiver or with the open air. These channels of communication are variously conducted and terminated, according to the views of the maker. The sketch in this figure is sufficient for explaining the principle, and is suited to the general form of the pump, as it has been frequently made by Nairne and other artists in London.

Superiority of this construction.

Let us now suppose the piston at the top of the barrel, that it applies to it all over, and that the air in the barrel is very much rarefied: In the common pump the piston valve is pressed hard down by the atmosphere, and continues shut till the piston gets far down, condenses the air below it beyond its natural state, and enables it to force up the valves. But here, as soon as the piston quits the top of the barrel, it leaves a void behind it; for no air gets in round the piston rod, and the valve at K is shut by the pressure of the atmosphere. There is nothing now to oppose the elasticity of the air below but the stiffness of the valve *b c*; and thus the expelling (or more accurately the liberating) force is prodigiously increased.

The superiority of this construction will be best seen by an example. Suppose the stiffness of the valve equal to the weight of 1-10th of an inch of mercury, when the barometer stands at 30 inches, and that the pump-gage stands at 29·9; then, in an ordinary pump, the valve in the piston will not rise till the piston has got within the 300th part of the bottom of the barrel, and it will leave the valve-hole filled with air of the ordinary density. But in this pump the valve will rise as soon as the piston quits the top of the barrel; and when it is quite down, the valve-hole *a* will contain only the 300th part of the air which it would have contained in a pump of the ordinary form. Suppose, farther, that the barrel is of equal capacity with the receiver.

and that both pumps are so badly constructed, that the space left below the piston is the 300th part of the barrel. In the common pump the piston valve will rise no more, and the rarefaction can be carried no farther, however delicate the barrel valve may be; but in this pump the next stroke will raise the gage to 29·95, and the piston valve will again rise as soon as the piston gets half way down the barrel.

The limit to the rarefaction by this pump depends chiefly on the space contained in the hole LK, and in the space *b c d* of the piston. When the piston is brought up to the top, and applied close to it, those spaces remain filled with air of the ordinary density, which will expand as the piston descends, and thus will retard the opening of the piston valve. The rarefaction will stop when the elasticity of this small quantity of air, expanded so as to fill the whole barrel (by the descent of the piston to the bottom), is just equal to the force requisite for opening the piston valve.

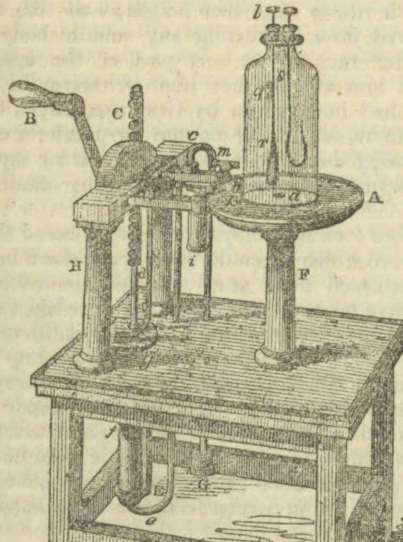
Another advantage attending this construction is, that in drawing up the piston, we are not resisted by the whole pressure of the air; because the air is rarefied above this piston as well as below it, and the piston is in precisely the same state of pressure as if connected with another piston in a double pump. The resistance to the ascent of the piston is the excess of the elasticity of the air above it over the elasticity of the air below; this, toward the end of the rarefaction, is very small, while the piston is near the bottom of the barrel, but gradually increases as the piston rises, and reduces the air above it into smaller dimensions, and becomes equal to the pressure of the atmosphere, when the air above the piston is of the common density. If we should raise the piston still farther, we must condense the air above it; but Mr. Smeaton has here made an issue for the air by a small hole in the top of the barrel, covered with a delicate valve. This allows the air to escape, and shuts again as soon as the piston begins to descend, leaving almost a perfect void behind it as before.

This pump has another advantage. It may be changed in a moment from a rarefying to a condensing engine, by simply turning the cocks at Q and T. Whilst T communicates with the open air and Q with the receiver, it is a rarefying engine or air-pump; but when T communicates with the receiver, and Q with the open air, it is a condensing engine.

Description of Smeaton's pump.

Fig. 26 represents Mr. Smeaton's air-pump as it was usually made by Nairne. Upon a solid base or table are set up three pillars F, H, H; the pillar F supports the pump-plate A, and the pillars H, H, support the front or head, containing a brass cog-wheel, which is turned by the handle B, and works in the rack C fastened to the upper end of the piston rod. The whole is still farther steadied by two pieces of brass *n* and *h*, which connect the pump-plate with the front, and have perforations communicating between the hole *a* in the middle of the plate and the barrel, as will be described immediately. DE is the barrel of the pump, firmly fixed to the table by screws through its upper flanch; *e f d c* is a slender brass tube screwed to the bottom of the barrel, and to the under side of the horizontal canal *n*. In this canal there is a cock *m*, which opens a communication between the barrel and the receiver, when the key is in the position represented here; but when the key is at right angles with this position, this communication is cut off. If that side of the key which is here drawn next to the pump-plate be turned outward, the external air is admitted into the receiver; but if turned inwards, the air is admitted into the barrel.

Fig. 26.



g h is another slender brass pipe, leading from the discharging valve at *g* to the horizontal canal *h k*, to the under side of which it is screwed fast. In this horizontal canal there is a cock *n* which opens a passage from the barrel to the receiver when the key is in the position here drawn; but opens a passage from the barrel to the external air when the key is turned outwards, and from the receiver to the external air when the key is turned inwards. This communication with the external air is not immediate but through a sort of box *i*; the use of this box is to receive the oil which is discharged through the top valve *g*. In order to keep the pump tight, and in working order, it is proper sometimes to pour a table-spoonful of olive oil into the hole *a* of the pump-plate, and then to work the pump. The oil goes along the conduit *b c d f e*, gets into the barrel and through the piston-valve, when the piston is pressed to the bottom of the barrel, and is then drawn up, and forced through the discharging valve *g* along the pipe *g h*, the horizontal passage *h n*, and finally into the box *i*. This box has a small hole in its side near the top, through which the air escapes.

From the upper side of the canal *n* there arises a slender pipe which bends outward and then turns downwards, and is joined to a small box, which cannot be seen in this view. From the bottom of this box proceeds downwards the gage-pipe of glass, which enters the cistern of mercury G fixed below.

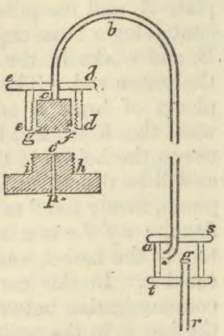
On the upper side of the other canal there is a small stud, having a short pipe of glass projecting horizontally from it, close by and parallel to the front piece of the pump, and reaching to the other canal. This pipe is close at the farther end, and has a small drop of mercury or oil in it. This serves as a gage in condensing, indicating the degree of condensation by the place of the drop; for this drop is forced along the pipe, condensing the air before it in the same degree that it is condensed in the barrel and receiver.

Method of joining together the different pipes, &c.

In constructing this pump, Mr. Smeaton introduced a method of joining together the different pipes and other pieces, which has great advantages over the usual manner of screwing them together with leather between, and which is now much used in hydraulic and pneumatic engines. We shall explain this to our readers by a description of the manner in which the exhausting gage is joined to the horizontal duct *c b*.

The piece *h i p*, in fig, 27, is the same with the little cylinder observable on the upper side of the horizontal canal *n*, in fig. 26. The upper part *h i* is formed into an outside screw, to fit the hollow screw of the piece *d e e d*. The top of this last piece has a hole in its middle, giving an easy passage to the bent tube *c b a*, so as to slip along it with freedom. To the end *c* of this bent tube is soldered a piece of brass *c f g*, perforated in continuation of the tube, and having its end ground flat on the top of the piece *h i p*, and also covered with a slip of thin leather strained across it and pierced with a hole in the middle.

Fig. 27.



It is plain from this form, that if the surface *f g* be applied to the top of *h i*, and the cover *d e e d* be screwed down on it, it will draw or press them together, so that no air can escape by the joint, and this without turning the whole tube *c b a* round, as is necessary in the usual way. This method is now adopted for joining together the conducting pipes of the machines for extinguishing fires, an operation which was extremely troublesome before this improvement.

The conduit pipe E *e f c* (fig. 26), is fastened to the bottom of the barrel, and the discharging pipe *g h* to its top, in the same manner. But to return to the gage; the bent pipe *c b a* (fig. 27), enters the box *s t* near one side, and obliquely, and the gage-pipe *q r* is inserted through its bottom towards the opposite side. The use of this box is to catch any drops of mercury which may sometimes be dashed up through the gage-pipe by an accidental oscillation. This, by going through the passages of the pump, would corrode them, and would act particularly on the joints, which are generally soldered with tin. When this happens to an air-pump, it must be cleaned with the most scrupulous attention, otherwise it will be quickly destroyed.

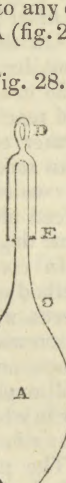
Great powers of this pump.

This account of Smeaton's pump is sufficient for enabling the reader to understand its operation and to see its superiority. It is reckoned a very fine pump of the ordinary construction which will rarefy 200 times, or raise the gage to 29·85, the barometer standing at 30. But Mr. Smeaton found, that his pump, even after long using, raised it to 29·95, which we consider as equivalent to rarefying 600 times. When in fine order, he found no bounds to its rarefaction, frequently raising the gage as high as the barometer; and he thought its performance so perfect,[1] that the barometer-gage was not sufficiently delicate for measuring the rarefaction. He therefore substituted the syphon-gage already described, which he gives some reasons for preferring; but even this he found not sufficiently sensible.

Another contrivance of Smeaton's.

He contrived another, which could be carried to any degree of sensibility. It consisted of a glass body A (fig. 28), of a pear shape, and was therefore called the pear-gage. This had a small projecting orifice at B, and at the other end a tube CD, whose capacity was the hundredth part of the capacity of the whole vessel. This was suspended at the slip-wire of the receiver, and there was set below it a small cup with mercury. When the pump was worked, the air in the pear-gage was rarefied along with the rest. When the rarefaction was brought to the degree intended, the gage was let down till B reached the bottom of the mercury. The external air being now let in, the mercury was raised into the pear, and stood at some height E in the tube CD. The length of this tube being divided into 100 parts, and those numbered from D, it is evident that $\frac{DE}{DB}$ will express the degree of rarefaction which had been produced when the gage was immersed into the mercury; or if DC be $\frac{1}{100}$ of the whole capacity, and be divided into 100 parts by a scale annexed to it, each unit of the scale will be $\frac{1}{10000}$ of the whole.

Fig. 28.



This was a very ingenious contrivance, and has been the means of making some very curious and important discoveries. By this gage Mr. Smeaton found, that his pump frequently rarefied a thousand, ten thousand, nay, an hundred thousand times. But though he in every instance saw the great superiority of his pump above all others, he frequently found irregularities which he could not explain, and a want of correspondence between the pear and the barometer gages which puzzled him. The pear-gage frequently indicated a prodigious rarefaction, when the barometer-gage would not show more than 600.

These unaccountable phenomena excited the curiosity of philosophers, who by this time were making continual use of the air-pump in their meteorological researches, and much interested in everything connected with the state or constitution of elastic fluids. Mr. Nairne, a most ingenious and accurate maker of philosophical instruments, made many curious experiments in the examination and comparison of Mr. Smeaton's pump with those of the usual construction, attending to every circumstance which could contribute to the inferiority of the common pumps or to their improvement, so as to bring them nearer to this rival machine. This rigorous comparison brought into view several circumstances in the constitution of the atmospheric air, and its relation to other bodies, which are of the most extensive and important influence in the operations of nature. We shall notice at present such only as have a relation to the operation of the air-pump in extracting AIR from the receiver.

Experiments wit it by Mr. Nairne.

Mr. Nairne found, that when a little water, or even a bit of paper damped with water, was exposed under the receiver of Mr. Smeaton's air-pump, when in the most perfect condition, raising the mercury in the barometer-gage to 29·95, he could not make it rise above 29·8 if Fahrenheit's thermometer indicated the temperature 47°, nor above 29·7 if the thermometer stood at 55°; and that to bring the gage to this height and keep it there, the operation of the pump must be continued for a long time after the water had disappeared or the paper become perfectly dry. He found that a drop of spirits, or paper moistened with spirits, could not in those circumstances allow the mercury in the gage to rise to near that height; and that similar effects followed from admittting any volatile body whatever into the receiver or any part of the apparatus. This showed him at once how improper were the directions which had been given by Guericke, Boyle, Gravesande, and others, for fitting up the air-pump for experiment, by soaking the leather in water, covering the joints with water, or in short, admitting water or any volatile body near it.

He therefore took his pumps to pieces, cleared them of all the moisture which he could drive from them by heat, and then leathered them anew with leather soaked in a mixture of olive oil and tallow, from which he had expelled all the water it usually contains, by boiling it till the first frothing was over. When the pumps were fitted up in this manner, he uniformly found that Mr. Smeaton's pump rarefied the gage to 29·95, and the best common pump to 29·87, the first of which he computed to indicate a rarefaction to 600, and the other to 230. But in this state he again found that a piece of damp paper, leather, wood, &c. in the receiver, reduced the performance in the same manner as before.

Remarkable phenomenon.

But the most remarkable phenomenon was, that when he made use of the pear-gage with the pump cleared from all moisture, it indicated the same degree of rarefaction with the barometer-gage; but when he exposed a bit of paper moistened with spirits, and thus reduced the rarefaction of the pump to what he called 50, the barometer-gage standing at 29·4, the pear-gage indicated a rarefaction exceeding 100,000. In short, it was not measurable; and this phenomenon was almost constant. Whenever he exposed any substance susceptible of evaporation, he found the rarefaction indicated by the barometer-gage greatly reduced, whilst that indicated by the pear-gage was prodigiously increased; and both these effects were the more remarkable as the subject was of easier evaporation, or the temperament of the air of the chamber was warmer.

---

[1] This can only be explained by supposing that Mr. Smeaton employed an imperfect barometer.

This uniform result suggested the true cause. Water boils at the temperature of 212°, that is, it is then converted into a vapour which is permanently elastic while of that temperature, and its elasticity balances the pressure of the atmosphere. If this pressure be diminished by rarefying the air above it, a low temperature will not allow it to be converted into elastic vapour, and keep it in that state. Water will boil in the receiver of an air-pump at the temperature of 96°, or even under it. Philosophers did not think of examining the state of the vapour in temperatures lower than what produced ebullition. But it now appears, that in much lower heats than this the superficial water is converted into elastic vapour, which continues to exhale from it as long as the water lasts, and, supplying the place of air in the receiver, exerts the same elasticity, and hinders the mercury from rising in the gage in the same manner as so much air of equal elasticity would have done.

Experiments illustrative of this account.

When Mr. Nairne was exhibiting these experiments to the Hon. Henry Cavendish in 1770, this gentleman informed him that it appeared from a series of experiments of his father Lord Charles Cavendish, that when water is of the temperature 72°, it is converted into vapour, under any pressure less than three-fourths of an inch of mercury, and at 41° it becomes vapour when the pressure is less than one-fourth of an inch: even mercury evaporates in this manner when all pressure is removed. A dewy appearance is frequently observed covering the inside of the tube of a barometer, where we usually suppose a vacuum. This dew, when viewed through a microscope, appears to be a set of detached globules of mercury, and upon inclining the tube so that the mercury may ascend along it, these globules will be all licked up, and the tube become clear. The dew which lined it was the vapour of the mercury condensed by the side of the tube; and it is never observed but when one side is exposed to a stream of cold air from a window, &c.

To return to the vapour in the air-pump receiver; it must be observed, that as long as the water continues to yield it, we may continue to work the pump; and it will be continually abstracted by the barrels, and discharged in the form of water, because it collapses as soon as exposed to the external pressure. All this while the gage will not indicate any more rarefaction, because the thing immediately indicated by the barometer-gage is *diminished elasticity*, which does not happen here. When all the water which the temperature of the room can keep elastic has evaporated under a certain pressure, suppose half an inch of mercury, the gage standing at 29·5, the vapour which now fills the receiver expands, and by its diminished elasticity the gage rises, and now some more water which had been attached to bodies by chemical or corpuscular attraction is detached, and a new supply continues to support the gage at a greater height; and this goes on continually till *almost* all has been abstracted. But there will remain some which no art can take away; for as it passes through the barrels, and gets between the piston and the top, it successively collapses into water during the ascent of the piston, and again expands into vapour when we push the piston down again. Whenever this happens there is an end of the rarefaction.

Air and vapour not uniformly mixed together.

Whilst this operation is going on, the air comes out along with the vapour; but we cannot say in what proportion. If it were always uniformly mixed with the vapour, it would diminish rapidly; but this does not appear to be the case. There is a certain period of rarefaction in which a transient cloudiness is perceived in the receiver. This is watery vapour formed at that degree of rarefaction, mingled with, but not dissolved in or united with, the air, otherwise it would be transparent. A similar cloud will appear if damp air be admitted suddenly into an exhausted receiver. The vapour, which formed an uniform transparent mass with the air, is either suddenly expanded and thus detached from the other ingredient, or is suddenly let go by the air, which expands more than it does. We cannot affirm with probability which of these is the case. Different compositions of air, that is, air loaded with vapours from different substances, exhibit remarkable differences in this respect. But we see from this and other phenomena, which shall be mentioned in their proper places, that the air and vapour are not always intimately united; and therefore will not always be drawn out together by the air-pump. But let them be ever so confusedly blended, we see that the air must come out along with the vapour, and its quantity remaining in the receiver must be prodigiously diminished by this association, probably much more than could be, had the receiver only contained pure air.

Consequences of this.

Let us now consider what must happen in the pear-gage. As the air and vapour are continually drawn off from the receiver, the air in the pear expands and goes off with it. We shall suppose that the generated vapour hinders the gage from rising beyond 29·5. During the continued working of the pump, the air in the pear, whose elasticity is 0·5, slowly mixes with the vapour at the mouth of the pear, and the mixture even advances into its inside, so that if the pumping be long enough continued, what is in the pear is nearly of the same composition with what is in the receiver, consisting perhaps of 20 parts of vapour and one part of air, all of the elasticity of 0·5. When the pear is plunged into the mercury, and the external air allowed to get into the receiver, the mercury rises in the pear-gage, and leaves not $\frac{1}{60}$, but $\frac{1}{60 \times 20}$ or $\frac{1}{1200}$ of it filled with common air, the vapour having collapsed into an invisible atom of water. Thus the pear-gage will indicate a rarefaction of 1200, while the barometer-gage only showed 60, that is, showed the elasticity of the included substance diminished 60 times. The conclusion to be drawn from these two measures (the one of the rarefaction of air, and the other of the diminution of elasticity) is, that the matter with which the receiver was filled, immediately before the readmission of the air, consisted of one part of incondensible air, and $\frac{1200}{60}$, or 20 parts of watery vapour.

Difficulty in accounting for some of these.

The only obscure part of this account is what relates to the composition of the matter which filled the pear-gage before the admission of the mercury. It is not easy to see how the vapour of the receiver comes in by a narrow mouth while the air is coming out by the same passage. Accordingly it requires a very long time to produce this extreme rarefaction in the pear-gage; and there are great irregularities in any two succeeding experiments, as may be seen by looking at Mr. Nairne's account of them.[1] Some vapours appear to have mixed much more readily with the air than others; and there are some unaccountable cases where vitriolic acid and sulphureous bodies were included, in which the dimunition of density indicated by the pear-gage was uniformly less than the diminution of elasticity indicated by the barometer-gage. It is enough for us at present to have established, by unquestionable facts, this production of elastic vapour, and the necessity of attending to it, both in the construction of the air-pump, and in drawing results from experiments exhibited in it.

---

[1] *Phil. Trans.* vol. lxvii.

Two new improvements.

Mr. Smeaton's pump, when in good order, and perfectly free from all moisture, will in dry weather rarefy air about 600 times, raising the barometer-gage to within $\frac{1}{20}$th of an inch of a fine barometer. This was a performance so much superior to that of all others, and by means of Mr. Nairne's experiments opened so new a field of observation, that the air-pumps once more became a capital instrument among the experimental philosophers. The causes of its superiority were also so distinct, that artists were immediately excited to a farther improvement of the machine ; so that this becomes a new epoch in its history.

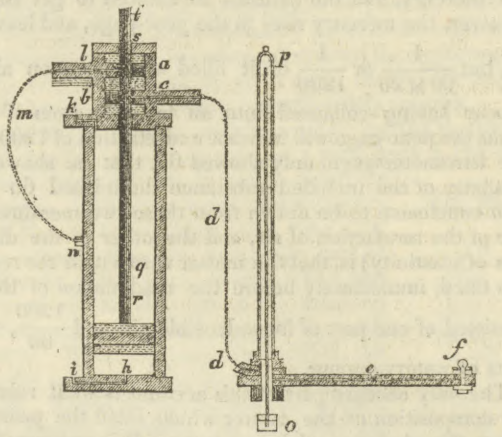
Improvements in this pump attempted.

There is one imperfection which Mr. Smeaton has not attempted to remove. The discharging valve is still opened against the pressure of the atmosphere. An author of the Swedish academy adds a subsidiary pump to this valve, which exhausts the air from above it, and thus puts it in the situation of the piston valve. We do not find that this improvement has been adopted so as to become general. Indeed the quantity of air which remains in the passage to this valve is so exceedingly little, that it does not seem to merit attention. Supposing the valve hole $\frac{1}{20}$th of an inch wide and as deep (and it need not be more), it will not occupy more than $\frac{1}{9000}$th part of a barrel twelve inches long and two inches wide.

Mr. Smeaton, by his ingenious construction, has greatly diminished, but has not annihilated, the obstructions to the passage of the air from the receiver into the barrel. His success encouraged farther attempts. One of the first and most ingenious was that of Professor Russell of the University of Edinburgh, who, about the year 1770, constructed a pump in which both cocks and valves were avoided.

The piston is solid, as represented in fig. 28, and its rod passes through a collar of leather on the top of the barrel. This collar is divided into three portions by two brass rings *a*, *b*, which leave a very small space round the piston rod. The upper ring *a* communicates by means of a lateral perforation with the bent tube, *l m n*, which enters the barrel at its middle *n*. The lower ring *b* communicates with the bent tube *c d*, which communicates with the horizontal passage *d e* going to the middle *e* of the pump plate. By the way, however, it communicates also with a barometer gage *p o*, standing in a cistern of mercury *o*, and covered with a glass tube close at the top. Beyond *e*, on the opposite circumference of the receiver plate, there is a cock or plug *f* communicating with the atmosphere.

Fig. 28.



The piston rod is closely embraced by the three collars of leather ; but, as already said, has a free space round it in the two brass rings. To produce this pressure of the leathers to the rod, the brass rings which separate them are turned thinner on the inner side, so that their cross section along a diameter would be a taper wedge. In the side of the piston rod are two cavities *q r*, *t s*, about one-tenth of an inch wide and deep, and of a length equal to the thickness of the two rings *a b*, and the intermediate collar of leathers. These cavities are so placed on the piston-rod, that when the piston is applied to the bottom of the barrel, the cavity *t s* in the upper end of the rod has its upper end opposite to the ring *a*, and its lower end opposite to the ring *b*, or to the mouth of the pipe *c d*. Therefore, if there be a void in the barrel, the air from the receiver will come from the pipe *c d*, into the cavity in the piston-rod, and by it will get past the collar of leather between the rings, and thus will get into the small interstice between the rod and the upper ring, and then into the pipe *l m n*, and into the empty barrel. When the piston is drawn up, the solid rod immediately shuts up this passage, and the piston drives the air through the discharging valve *k*. When it has reached the top of the barrel, and is closely applied to it, the cavity *q r* is in the situation in which *t s* formerly was, and the communication is again opened between the receiver and the empty barrel, and the air is again diffused between them. Pushing down the piston expels the air by the lower discharging pipe and valve *h i*; and thus the operation may be continued.

This must be acknowledged to be a most simple and ingenious construction, and can neither be called a cock nor a valve. It seems to oppose no obstruction whatever ; and it has the superior advantage of rarefying both during the ascent and the descent of the piston, doubling the expedition of the performance, and the operator is not opposed by the pressure of the atmosphere except towards the end of each stroke. The expedition, however, is not so great as one should expect ; for nothing is going on while the piston is in motion, and the operator must stop a while at the end of each stroke, that the air may have time to come through this long, narrow, and crooked passage, to fill the barrel. But the chief difficulty which occurred in the execution arose from the clammy oil with which it was necessary to impregnate the collar of leathers. These were always in a state of strong compression, that they might closely grasp the piston rod, and prevent all passage of air during the motion of the piston. Whenever therefore the cavities in the piston rod come into the situations necessary for connecting the receiver and barrel, this oil is squeezed into them, and choaks them up. Hence it always happened that it was some time after the stroke before the air could force its way round the piston rod, carrying with it the clammy oil which choaked up the tube *l m n;* and when the rarefaction had proceeded a certain length, the diminished elasticity of the air was not able to make its way through these obstructions.

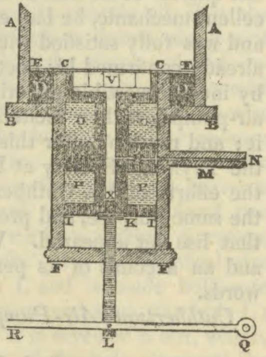
Mr. Cavallo[1] has given the description of an air-pump contrived and executed by Messrs Hans and Hurter, instrument makers in London, where these artists revived Guericke's method of opening the barrel-valve during the last strokes of the pump by a force acting from without. We shall insert as much of this description as relates to the distinguishing circumstance of its construction.

---

[1] *Phil. Trans.* vol. lxxiii.

Fig. 29 represents a section of the bottom of the barrel, where AA is the barrel, and BB the bottom, which has in its middle a hollow cylinder CCFF, projecting about half an inch into the barrel at CC, and extending a good way downwards to FF. The space between this projection and the sides of the barrel is filled up by a brass ring DD, over the top of which is strained a piece of oiled silk EE, which performs the office of a valve, covering the hole CC. But this hole is filled up by a piece of brass, or rather an assemblage of pieces screwed together GG, HH, II. It consists of three projecting fillets or shoulders GG, HH, II, which form two hollows between them, and which are filled with rings of oiled leather OO, PP, firmly screwed together. The extreme fillets GG, II, are of equal diameter with the inside of the cylinder, so as to fill it exactly, and the whole stuffed with oiled leather, slide up and down without allowing any air to pass. The middle fillet HH is not so broad, but thicker. In the upper fillet GG there is formed a shallow dish about $\frac{1}{8}$ of an inch deep and $\frac{3}{4}$ wide. This dish is covered with a thin plate, pierced with a grating like Mr. Smeaton's valve plate. There is a perforation VX along the axis of this piece, which has a passage out at one side H, through the middle fillet. Opposite to this passage, and in the side of the cylinder CC,FF, is a hole M, communicating with the conduit pipe MN, which leads to the receiver. Into the lower end of the perforation is screwed the pin KL, whose tail L passes through the cap FF. The tail L is connected with a lever RQ, moveable round the joint Q. This lever is pushed upwards by a spring, and thus the whole piece which we have been describing is kept in contact with the slip of oiled silk or valve EE. This is the usual situation of things.

Fig. 29.



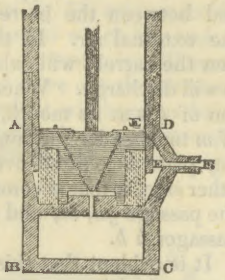
Now suppose a void formed in the barrel by drawing up the piston; the elasticity of the air in the receiver, in the pipe MN, and in the passage XV, will press on the great surface of the valve exposed through the grating, will raise it, and the pump will perform precisely as Mr. Smeaton's does. But suppose the rarefaction to have been so long continued, that the air is no longer able to raise the valve; this will be seen by the mercury rising no more in the pump-gage. When this is perceived, the operator must press with his foot on the end R of the lever RQ. This draws down the pin KL, and with it the whole hollow plug with its grated top. And thus, instead of raising the valve from its plate, the plate is here drawn down from the valve. The air now gets in without any obstruction whatever, and the rarefaction proceeds as long as the piston rises. When it is at the top of the barrel, the operator takes his foot from the lever, and the spring presses up the plug again and shuts the valve. The piston rod passes through a collar of leather, as in Mr. Smeaton's pump, and the air is finally discharged through an outward valve in the top of the barrel. These parts have nothing peculiar in them.

This is an ingenious contrivance, similar to what was adapted by Guericke himself; and we have no doubt of these pumps performing extremely well if carefully made; and it seems not difficult to keep the plug perfectly air-tight by supplying plenty of oil to the leathers. We cannot say, however, with precision, what may be expected from it, as no account has been given of its effects, besides what Mr. Cavallo published in the *Philosophical Transactions* for 1783, where he only says, that when it had been long used, it had, in the course of some experiments, rarefied 600 times.

Prince.

Aiming still at the removing the obstructions to the entry of the air from the receiver into the barrels, Mr. Prince, an American, has constructed a pump in which there is no valve or cock whatever between them. In this pump the piston rod passes through a collar of leather, and the air is finally discharged through a valve, as in the two last. But we are chiefly to attend, in this place, to the communication between the barrel and the receiver. The barrel widens below into a sort of cistern ABCD, communicating with the receiver by the pipe EF. As soon, therefore, as the piston gets into this wider part, where there is a vacancy all round it, the air of the receiver expands freely through the passage FEE into the barrel, in which the descent of the piston had made a void. When the piston is again drawn up, as soon as it gets into the cylindric part of the barrel, which it exactly fills, it carries up the air before it, and expels it by the top valve; and, that this may be done more completely, this valve opens into a second barrel or air-pump whose piston is rising at the same time, and therefore the valve of communication (which is the discharging valve of the primary pump) opens with the same facility as Mr. Smeaton's piston valve. While the piston is rising, the air in the receiver expands into the barrel; and when the piston descends, the air in the barrel again collapses till the piston gets again into the cistern, when the air passes out, and fills the evacuated barrel, to be expelled by the piston as before.

Fig. 30.



No distinct account has yet been given of the performance of this pump. We only learn that great inconveniences were experienced from the oscillations of the mercury in the gage. As soon as the piston comes into the cistern, the air from the receiver immediately rushes into the barrel, and the mercury shoots up in the gage, and gets into a state of oscillation. The subsequent rise of the piston will frequently keep time with the second oscillation, and increase it. The descent of the piston produces a downward oscillation, by allowing the air below it to collapse; and by improperly timing the strokes, this oscillation becomes so great as to make the mercury enter the pump. To prevent this, and a greater irregularity of working as a condenser, valves were put in the piston; but as these require force to open them, the addition seemed rather to increase the evil, by rendering the oscillations more simultaneous with the ordinary rate of working.

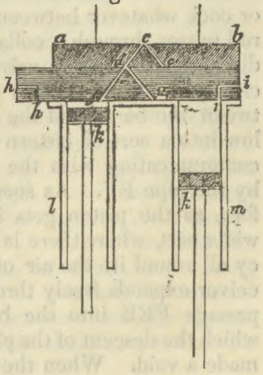
It appears, however, of very difficult execution. It has many long, slender, and crooked passages, which must be drilled through broad plates of brass, some of them appearing scarcely practicable. It is rare to find plates and other pieces of brass without air-holes, which it would be very difficult to find out and to close; and it must be very difficult to clear it of obstructions; so that it appears rather a suggestion of theory than a thing warranted by its actual performance.

Lavoisier.

M. Lavoisier, or some of the naturalists who were occupied in concert with him in the investigation of the different species of gas which are disengaged from bodies in the course of chemical operations, contrived an air-pump which has great appearance of simplicity, and, being very different from all others, deserves to be taken notice of.

It consists of two barrels *l m*, (fig. 31) with solid pistons *k k*. The pump plate *a b*, is pierced at its centre *c* with a hole which branches towards each of the barrels, as represented by *c d*, *c e*. Between the plate and the barrels slides another plate *h i*, pierced in the middle with a branched hole *f d g*, and near the ends with two holes *h h*, *i i*, which go from its under side to the ends. The holes in these two plates are so adjusted, that when the plate *h i* is drawn so far towards *h* that the hole *i* comes within the barrel *m*, the branch *d f* of the hole in the middle plate coincides with the branch *cd* of the upper plate, and the holes *e g* are shut. Thus a communication is established between the barrel *l* and the receiver on the pump-plate, and between the barrel *m* and the external air. In this situation the barrel *l* will exhaust, and *m* will discharge. When the piston of *l* is at its mouth, and that of *m* touches its bottom, the sliding plate is shifted over to the other side, so that *m* communicates with the receiver through the passage *gd*, *ec*, and *l* communicates with the air by the passages *h h*.

Fig. 31.



It is evident that this sliding plate performs the office of four cocks in a very beautiful and simple manner, and that if the pistons apply close to the ends of the barrels so as to expel the whole air, the pump will be perfect. It works, indeed, against the whole pressure of the external air. But this may be avoided by putting valves on the holes *h i*; and these can do no harm, because the air remaining in them never gets back into the barrel till the piston be at the farther end, and the exhaustion of that stroke completed. But the best workmen of London think that it will be incomparably more difficult to execute this cock (for it is a cock of an unusual form), in such a manner that it shall be air-tight and yet move with tolerable ease, and that it is much more liable to wearing loose than common cocks. No accurate accounts have been received of its performance. It must be acknowledged to be ingenious, and it may suggest to an intelligent artist a method of combining common conical cocks upon one axis so as to answer the same purposes much more effectually; for which reason we have inserted it here.

Cuthbertson.

The last improvement which we shall mention, is that published by Mr. Cuthbertson. His pump has given such evidences of its perfection, that we can hardly expect or wish for any thing more complete. But we must be allowed to observe, beforehand, that the same construction was invented, and in part executed, before the end of 1779, by Dr. Daniel Rutherford, then professor of botany in the University of Edinburgh, who was at that time engaged in experiments on the production of air during the combustion of bodies in contact with nitre, and who was vastly desirous of procuring a more complete abstraction of pure aerial matter than could be effected by Mr. Smeaton's pump. The compiler of this article had then an opportunity of perusing the Doctor's dissertation on this subject, which was read in the Philosophical Society of Edinburgh. In this dissertation he appears fully apprised of the existence of pure vital air in the nitrous acid, as its chief ingredient, and as the cause of its most remarkable phenomena, and to want but a step to the discoveries which have ennobled the name of M. Lavoisier. He was particularly anxious to obtain *apart* this distinguishing ingredient in its composition, and, for this purpose, to abstract completely from the vessel in which he subjected it to examination, every particle of elastic matter. The writer of this article proposed to him to cover the bottom of Mr. Smeaton's piston with some clammy matter, which should take hold of the bottom valve, and *start it* when the piston is drawn up. A few days after, the Doctor showed him a drawing of a pump, having a conical metal valve in the bottom, furnished with a long slender wire, sliding in the inside of the piston-rod with a gentle friction, sufficient for lifting the valve, and secured against all chance of failure by a spring a-top, which took hold of a notch in the inside of the piston-rod about a quarter of an inch from the lower end, so as certainly to lift the valve during the last quarter of an inch of the piston's motion. Being an excellent mechanic, he had executed a valve on this principle, and was fully satisfied with its performance. But having already confirmed his doctrines respecting the nitrous acid by incontrovertible experiments, his wishes to improve the air-pump lost their incitement, and he thought no more of it; and not long after this the ardour of the philosophers of the Teylerian Society at Haerlem and Amsterdam excited the efforts of Mr. Cuthbertson, their instrument maker, to the same purpose, and produced the most perfect air-pump that has yet appeared. We shall give a description of it, and an account of its performance, in the inventor's own words.

Cuthbertson's Air-Pump.—On fig. 32 is a perspective view of Cuthbertson's pump, with its two principal gages screwed into their places. These need not be used together, except in cases where the utmost exactness is required. In common experiments one of them is removed, and a stop-screw put in its place. When the pear-gage is used, a small round plate, on which the receiver may stand, must be first screwed into the hole at A; but this hole is stopped on other occasions with a screw. When all the three gages are used, and the receiver is exhausted, the stop-screw B, at the bottom of the pump, must be unscrewed, to admit the air into the receiver; but when they are not all used, either of the other stop-screws will answer this purpose.

Fig. 32.

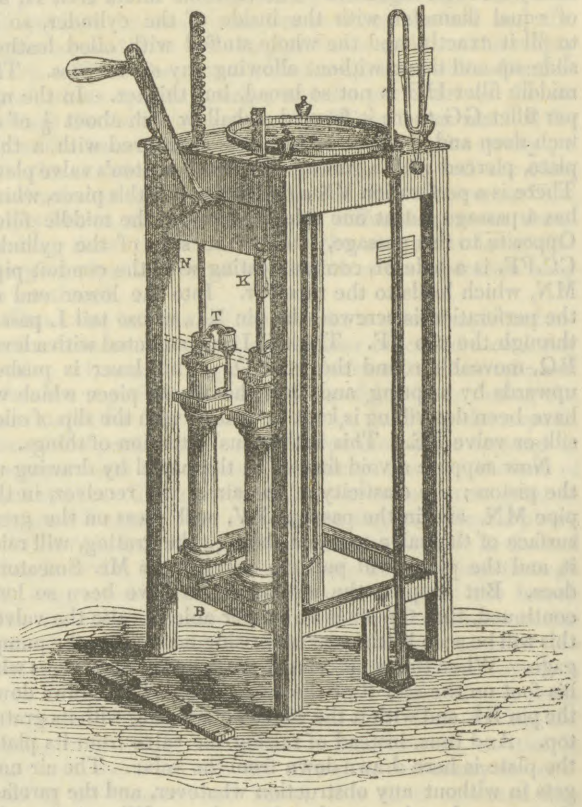


Fig 33 represents a cross bar for preventing the barrels from being shaken by working the pump or by any accident. Its place in fig. 32 is represented by the dotted lines.

Fig. 33.

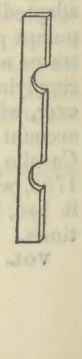

Fig. 34 is a section of one of the barrels, with all its internal parts; and figs. 35, 36, 37, and 38, are different parts of the piston, proportioned in size to one another.[1]

In fig. 34 CD represents the barrel, F the collar of leathers, G a hollow cylindrical vessel to contain oil, R is also an oil-vessel to receive the oil which is drawn, along with the air, through the hole *a a*, when the piston is drawn upwards; and, when this is full, the oil is carried over with the air, along the tube T, into the oil-vessel G, *c c* is a wire which is driven upwards from the hole *a a* by the passage of the air; and as soon as this has escaped, it falls down again by its own weight, shuts up the hole, and prevents all return of the air into the barrel. At *d d* are fixed two pieces of brass, to keep the wire *c c* in a vertical direction, that it may accurately shut the hole. H is a cylindrical wire or rod which carries the piston I, and is made hollow to receive a long wire *g g*, which opens and shuts the hole L; and on the other end of the wire O is screwed a nut, which, by stopping in the narrowest part of the hole, prevents the wire from being driven up too far. This wire and screw are more clearly seen in figs. 35 and 39; they slide in a collar of leather *r*, figs. 35 and 38, in the middle piece of the piston. Figs. 37 and 38 are the two main parts which compose the piston, and when the pieces 36 and 39 are added to it the whole is represented by fig. 35. Fig. 38 is a piece of brass of a conical form, with a shoulder at the bottom. A long hollow screw is cut in it, about two-thirds of its length, and the remainder of the hole, in which there is no screw, is of about the same diameter with the screwed part, except a thin plate at the end, which is of a width exactly equal to the thickness of *g g*, fig. 34. That part of the inside of the conical brass in which no thread is cut, is filled with oiled leathers with holes through which *g g* can slide stifly. There is also a male screw with a hole in it, fitted to *g g*, serving to compress the leathers *r*. In fig. 37, *a a a a* is the outside of the piston, the inside of which is turned so as exactly to fit the outside of fig. 38; *b b* are round leathers about 60 in number, *c c* is a circular piece of brass of the size of the leathers, and *d d* is a screw serving to compress them. The screw at the end of fig. 36 is made to fit the screw in fig. 38. Now if fig. 39 be pushed into fig. 38, this into fig. 37, and fig. 36 be screwed into the end of fig. 38, these will compose the whole of the piston, as represented in fig. 34. H, in fig. 34, represents the same part as H in fig. 35, and is that to which the rack is fixed. If, therefore, this be drawn upwards, it will cause fig. 38 to shut close into fig. 37, and drive out the air above it; and when it is pushed downwards it will open as far as the shoulder *a a* will permit, and suffer air to pass through. AA (fig. 40) is the receiver plate, BB is a long square piece of brass, screwed into the under side of the plate, through which a hole is drilled corresponding to that in the centre of the receiver-plates and with three female screws *a*, *b*, *c*.

Fig. 34.

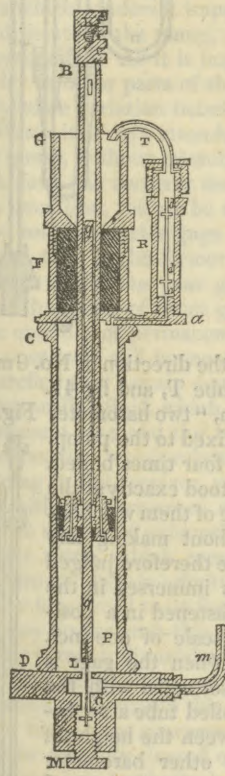

Fig. 35.

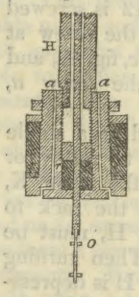

Fig. 36.

Fig. 37.

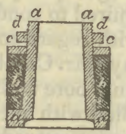

Fig. 38.

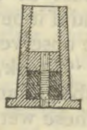

Fig 39.

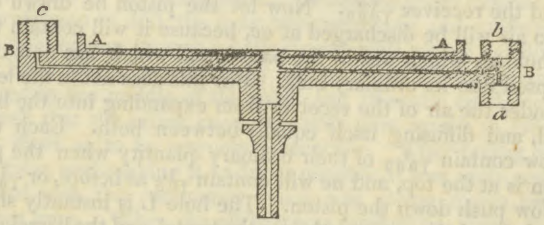
Fig. 40.



The rarefaction of the air in the receiver is effected as follows. Suppose the piston at the bottom of the barrel. The inside of the barrel, from the top of the piston to *a*, (fig. 34) contains common air. When the rod is drawn up, the outer part of the piston sticks fast in the barrel till the conical part connected with the rod shuts the conical hole, and its shoulder applies close to its bottom. The piston is now shut, and therefore the *whole* is drawn up by the rack-work, driving the air before it through the hole *a c*, into the oil-vessel at R, and out into the room by the tube T. The piston will then be at the top of the barrel at *a*, and the wire *gg* will stand nearly as represented in the figure just raised from the hole L, and prevented from rising higher by the nut O. During this motion the air will expand in the receiver, and come along the bent tube *m* into the barrel. Thus the barrel will be filled with air, which, as the piston rises, will be rarefied in proportion as the capacity of the receiver, pipes, and barrel, is to the barrel alone. When the piston is moved down again by the rack-work, it will force the conical part (fig. 38) out of the hollow part (fig. 37) as far as the shoulders *a a*; fig. 35 will rest on *a a* (fig. 37) which will then be so far open as to permit the air to pass freely through it, while at the same time the end of *g g* is forced against the top of the hole, and shuts it, in order to prevent any air from returning into the receiver. Thus the piston, moving downwards, suffers the air to pass out between the sides of figs. 37 and 38; and, when it is at the bottom of the barrel, will have the column of air above it; and, consequently, when drawn upwards it will shut, and drive out this air, and, by opening the hole L at the same time, will give a free passage to more air from the receiver. This process being continued, the air of the receiver will be rarefied as far as its expansive power will permit. For in this machine there are no valves to be forced open by the elasticity of the air in the receiver, which at last it is unable to effect. There is therefore nothing to prevent the air from expanding to its utmost degree.

---

[1] The piston and barrel are 1·65 inches in diameter, in proportion to which the scale is drawn. Figures 35, 36, 37, and 38, are, however, of double size.

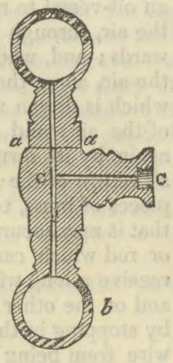
It may be suspected here, that as the air must escape through the discharging passage *ac*, fig. 34, against the pressure of a column of oil and the weight of the wire, there will remain in this passage a quantity of air of considerable density, which will expand again into the barrel during the descent of the piston, and thus put a stop to the progress of rarefaction. This is the case in Mr. Smeaton's pump, and all which have valves in the piston. But it is the peculiar excellency of this pump, that whatever be the density of the air remaining in *ac*, the rarefaction will still go on. It is worth while to be perfectly convinced of this. Let us suppose that the air contained in *ac* is $\frac{1}{100}$th part of the common air which would fill the barrel, and that the capacity of the barrel is equal to that of the receiver and passages, and that the air in the receiver and barrel is of the same density, the piston being at the bottom of the barrel: the barrel will therefore contain $\frac{10}{1000}$ parts of its natural quantity, and the receiver $\frac{10}{1000}$. Now let the piston be drawn up. No air will be discharged at *ac*, because it will contain the whole air which was in the barrel, and which has now collapsed into its ordinary bulk. But this does not in the least hinder the air of the receiver from expanding into the barrel, and diffusing itself equally between both. Each will now contain $\frac{5}{1000}$ of their ordinary quantity when the piston is at the top, and *ac* will contain $\frac{1}{100}$ as before, or $\frac{10}{1000}$. Now push down the piston. The hole L is instantly shut, and the air in *ac* expands into the barrel, and the barrel now contains $\frac{15}{1000}$. When the piston has reached the bottom, let it be again drawn up. There will be $\frac{5}{1000}$ discharged through *c*, and the air in the receiver will again be equally distributed between it and the barrel. Therefore the receiver will now contain $\frac{2\frac{1}{2}}{1000}$. When the piston reaches the bottom, there will be $\frac{12\frac{1}{2}}{1000}$ in the barrel. When again drawn up to the top, there will be $\frac{2\frac{1}{2}}{1000}$ discharged, and the receiver will contain $\frac{1\frac{1}{4}}{1000}$; and when the piston reaches the bottom, there will be $\frac{11\frac{1}{4}}{1000}$. At the next stroke the receiver will contain only $\frac{0\cdot\frac{5}{8}}{1000}$, &c. &c.

Thus it appears, that notwithstanding the $\frac{10}{1000}$ which always expands back again out of the hole *ac* into the barrel, the rarity of the air in the receiver will be doubled at every stroke. There is therefore no need of a subsidiary air-pump at *c*, as in the American air-pump, and in the Swedish attempt to improve Smeaton's.

In using this air-pump no particular directions are necessary, nor is any peculiar care necessary for keeping it in order, except that the oil-vessel A be always kept about half full of oil. When the pump has stood long without being used, it will be proper to draw a table-spoonful of olive-oil through it, by pouring it into the hole in the middle of the receiver-plate when the piston is at the bottom of the barrel. Then by working the piston, the oil will be drawn through all the parts of the pump, and the surplus will be driven through the tube T into the oil-vessel G. Near the top of the piston rod at H, there is a hole which lets some oil into the inside of the rod, which gets at the collar of leathers *rr*, and keeps the wire *gg* air-tight.

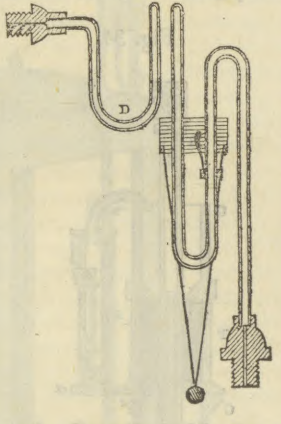
When the pump is used for condensation at the same time that it rarifies, or separately, the piece containing the bent tube T must be removed, and fig. 41 put into its place, and fixed by its screws. Fig. 41, as drawn in the plate, is intended for a double-barrelled pump. But for a single barrel only one piece is used, represented by *b a a*, the double piece being cut off at the dotted line *a a*. In this piece is a female screw to receive the end of a long brass tube, to which a bladder (if sufficient for the experiment of condensation,) or a glass, properly secured for this purpose, must be screwed. Then the air which is abstracted from the receiver on the pump-plate will be forced into the bladder or glass. But if the pump be double, the apparatus fig. 41 is used, and the long brass tube screwed on at *c*.[1]

Fig. 41.



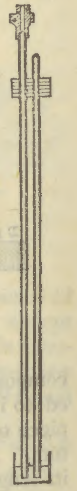
Figs. 42 and 43 represent the two gages, which will be sufficiently explained afterwards. Fig. 42 is screwed into *b*, or into the screw at the other end *c*, fig. 40, and fig 43 into the screw *a*, fig. 40.

Fig. 42.



If it be used as a single pump, either to rarefy or to condense, the screw K, which fastens the rack to the piston rod H, must be taken out. Then turning the winch till H is depressed as low as possible, the machine will be fitted to exhaust as a single pump; and if it be required to condense, the direction in No. 8 must be observed with regard to the tube T, and fig 41.

Fig. 43.



"I took," says Mr. Cuthbertson, "two barometer tubes of an equal bore with that fixed to the pump. These were filled with mercury four times boiled. They were then compared, and stood exactly at the same height. The mercury in one of them was boiled in it four times more, without making any change in their height; they were therefore judged very perfect. One of these was immersed in the cistern of the pump gage, and fastened in a position parallel to it, and a sliding scale of one inch was attached to it. This scale, when the gage is used, must have its upper edge set equal with the surface of the mercury in the boiled tube after exhaustion, and the difference between the height of the mercury in this and in the other barometer tube may be observed to the $\frac{1}{100}$ of an inch; and being close together, no error arises from their not being exactly vertical, if they are only parallel. This gage will be better understood by inspecting fig. 43.

"I used a second gage, which I shall call a double syphon. (See fig. 42.) This was also prepared with the utmost care. I had a scale for measuring the difference between the height of the columns in the two legs. It was an inch long, and divided as the former, and kept in a truly vertical position by suspending it from a point with a weight hung to it, as represented in the figure. Upon comparing these two gages, I always found them to indicate the same degree of rarefaction. I also used a pear-gage, though the most imperfect of all, in order to repeat the curious experiments of Mr. Nairne and others."

---

[1] An air-pump of this description is by far too delicate to be employed without risk of injury in experiments on condensed air.

When experiments require the utmost rarefying power of the pump, the receiver must not be placed on leather, either oiled or soaked in water, as is usually done. The pump plate and the edge of the receiver must be ground very flat and true, and this with very fine emery, that no roughness may remain. The plate of the pump must then be wiped very clean and very dry, and the receiver rubbed with a warm cloth till it become electrical. The receiver being now set on the plate, hog's lard, either alone or mixed with a little oil which has been cleared of water by boiling, must be smeared round its outside edge. In this condition the pump will rarefy its utmost, and what still remains in the receiver will be permanent air. Or a little of this composition may be thinly smeared on the pump plate; this will prevent all risk of scratching it with the edge of the receiver. Leather of very uniform thickness, long dried before a fire, and well soaked in this composition, which must be cleared of all water by the first boiling, will answer very well, and is expeditious, when receivers are to be frequently shifted. Other leathers should be at hand soaked in a composition containing a little rosin. This gives it a clamminess which renders it impermeable to air, and is very proper at all joints of the pump, and all apparatus for pneumatic experiments. As it is impossible to render the pear-gage as dry as other parts of the apparatus, there will be generally some variation between this and the other gages.

When it is only intended to show the utmost power of the pump, without intending to ascertain the quality of the residuum, the receiver may be set on wet leather. If, in this condition, the air be rarefied as far as possible, the syphon and barometer gage will indicate a less degree of rarefaction than in the former experiments. But when the air is let in again, the pear gage will point out a rarefaction some thousands of times greater than it did before If the true quantity of permanent air after exhaustion be required, the pear gage will be nearest the truth; for when the air is rarefied to a certain degree, the moistened leather emits an expansible fluid, which, filling the receiver, forces out the permanent air; and the two first gages indicate a degree of exhaustion which relates to the whole elastic matter remaining in the receiver, viz. to the expansible fluid together with the permanent air; whereas the pear gage points out the degree of exhaustion, with relation to the permanent air alone, which remains in the receiver; for by the pressure of the air admitted into the receiver, the elastic vapour is reduced to its former bulk, which is imperceptible.

Many bodies emit this elastic fluid when the pressure of the air is much diminished; a piece of leather, in its ordinary damp state, about an inch square, or a bit of green or dry wood, will supply this for a great while. When such fluids have been generated in any experiments, the pump must be carefully cleared of them, for they remain not only in the receiver, but in the barrels and passages, and will again expand when the exhaustion has been carried far.

The best method of clearing the pump is to take a very large receiver, and, using every precaution, to exhaust it as far as possible. Then the expansible matter lurking in the barrels and passes will be diffused through the receiver also, or will be carried off along with its air. It will be as much rarer than it was before, as the aggregate capacity of the receiver, barrels and passes is larger than that of the two last.

The performance of the pump may be judged of from the four following experiments: The two gages being screwed into their places, and the hole in the receiver-plate shut up the pump was made to exhaust as far as it could. The mercury in the legs of the syphon was only $\frac{1}{40}$ of an inch out of the level, and that in the boiled barometer-tube $\frac{1}{40}$ of an inch higher than in the one screwed to the pump. A standard barometer then stood at 30 inches, and therefore the pump rarefied the permanent air 1200 times. This is twice as much as Mr. Nairne found Mr. Smeaton's do in its best state. Mr. Cavallo seems disposed to give a favourable account of Haas and Hurter's pump, and it appears never to have exceeded 600 times. Mr. Cuthbertson has often found the mercury within $\frac{1}{100}$ of an inch of the level in the syphon-gage, indicating a rarefaction of 3000.[1]

To one end of a glass tube, two inches diameter and thirty inches long, was fitted a brass cap and collar of leather, through which a wire was inserted, reaching about two inches within the tube. This was connected with the conductor of an electric machine. The other end was ground flat and set on the pump plate. When the gages indicated a rarefaction of 300, the light became steady and uniform, of a pale colour, though a little tinged with purple; at 600 the light was of a pale dusky white; when 1200 it disappeared in the middle of the tube, and the tube conducted so well that the prime conductor only gave sparks so faint and short as to be scarcely perceptible. After taking off the tube, and making it as dry as possible, it was again connected with the conductor, which was giving sparks two inches long. When the air in it was rarefied ten times, the sparks were of the same length. Sometimes a pencil of light darted along the tube. When the rarefaction was 20, the spark did not exceed an inch, and light streamed the whole length of the tube. When the rarefaction was 30, the sparks were half an inch, and the light rushed along the tube in great streams. When the rarefaction was 100, the sparks were about $\frac{1}{8}$ long, and the light filled the tube in an uninterrupted body. When 300, the appearances were as before. When 600, the sparks were $\frac{1}{10}$, and the light was of a faint white colour in the middle, but tinged with purple toward the ends. When 1200, the light was hardly perceptible in the middle, and was much fainter at the ends than before, but still ruddy. When 1400, which was the most the pump could produce, six inches of the middle of the tube were quite dark, and the ends free of any tinge of red, and the sparks did not exceed $\frac{1}{40}$ of an inch.[2]

The best improvements of the air-pump made in Britain.

We trust that our readers will not be displeased with the preceding history of the air-pump. The occasional information which it gives will be of great use to every person much engaged in pneumatic experiments, and help him in the contrivance and construction of the necessary apparatus. We may be indulged in one remark, that although this noble instrument originated in Germany, all its improvements were made in this kingdom. Both the mechanical and pneumatical principles of Mr. Boyle's construction were extremely different from the German, and, in respect of expedition and conveniency, much superior. The double barrel and gage by Hawkesbee were capital improvements, and on principle; and Mr. Smeaton's method of making the piston work in rarefied air made a complete change in the whole process.

Utility of the air-pump.

Aided by this machine, we can make experiments establishing and illustrating the gravity and elasticity of the air, in a much more perspicuous manner than could be done by the spontaneous phenomena of nature. It allows us in the

---

[1] We are disposed to place most reliance on the experiment where $\frac{1}{1200}$ is stated as the limit of exhaustion, particularly as this result corresponds with the best information we have been able to obtain, regarding the performance of various very fine instruments.

[2] Since this article was originally written, a mathematical instrument maker of Edinburgh has invented an air-pump, possessing all the ad-

Air-pump.

first place to show the materiality of air in a very distinct manner. Bodies cannot move about in the atmosphere without displacing it. This requires force; and the resistance of the air always diminishes the velocity of bodies moving in it. A heavy body therefore has the velocity of its fall diminished; and if the quantity of air displaced be very great, the diminution will be very considerable. This is the reason why light bodies, such as feathers, fall very slowly. Their moving force is very small, and can therefore displace a great quantity of air only with a very small velocity. But if the same body be dropped *in vacuo*, when there is no air to be displaced, it falls with the whole velocity competent to its gravity. Fig. 44 represents an apparatus by which a guinea and a downy feather are dropped at the same instant. If this be done after the air has been pumped out, the guinea and the feather will be observed to reach the bottom at the same instant.

Fig. 44.

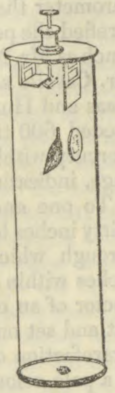


Fig. 45 represents another apparatus for showing the same thing. It consists of two sets of brass vanes put on separate axles, in the manner of windmill sails. One set has their edges placed in the direction of their whirling motion, that is, in a plane to which the axis is perpendicular. The planes of the other set pass through the axis, and they are therefore trimmed so as directly to front the air through which they move. Two springs act upon pins projecting from the axis; and their strength or tensions are so adjusted, that when they are disengaged *in vacuo*, the two sets continue in motion equally long. If they are disengaged in the air, the vanes which beat the air with their planes will stop long before those which cut it edgewise.

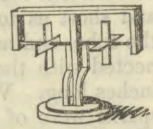
Fig. 45.

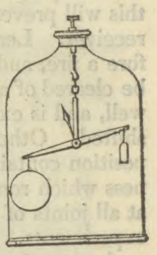


We can now abstract the air most completely from a dry vessel, so as to know the precise weight of the air which filled it. The first experiment we have of this kind, done with accuracy, is that of Dr. Hooke, February 10, 1664, when he found 114 pints of air to weigh 945 grains. One pint of water was $8\frac{7}{32}$ ounces. This gives for the specific gravity of air $\frac{1}{850}$ very nearly.

The effect of air on the weight of bodies immersed in it.

Since we are thus immersed in a gravitating fluid, it follows, that every body preponderates only with the excess of its own weight above that of the air which it displaces; for every body loses by this immersion the weight of the displaced air. A cubic foot loses about 521 grains in frosty weather. We see balloons even rise in the air, as a piece of cork rises in water. A mass of water which really contains 850 pounds will load the scale of a balance with 849 only, and will be balanced by about $849\frac{1}{8}$ pounds of brass. This is evinced by a very pretty experiment, represented in fig. 46. A small beam is suspended within a receiver. To one end of the beam is appended a thin glass or copper ball, close in every part. This is balanced by a small piece of lead hung on the other arm. As the air is pumped out of the receiver, the ball will gradually preponderate, and will regain its equilibrium when the air is re-admitted.

Fig. 46.



Some naturalists have proposed, and actually used, a large globe of light make, suspended at a beam, for a barometer. If its capacity be a cubic foot, $1\frac{7}{10}$ grains will indicate the

---

vantages of Mr. Cuthbertson's, with this other in addition, that it is much simpler in its construction. Fig. 1 presents a view of this pump. A A are the barrels, B the pipe leading from them to C, the receiver plate D the barometer gage, E a stop-cock for re-admitting the air, or for attaching a syphon gage, or other piece of apparatus. Fig. 2 is a section of the piston, and of the under part of one of the barrels, shewing the whole of the internal construction; A A, *a a* is the barrel, O N the piston, G I the piston rod containing the rod *r*, which slides in the collar of leathers T, and opens the valve *v e*; in this respect it is precisely the same as Cuthbertson's, but the maker dispenses with all the apparatus at the top of Cuthbertson's barrels, and has only an oiled silk valve S, in the piston, which is exposed to the atmosphere, as in Hook's pump. The exclusion of the atmosphere from the piston valve, the maker considers as unnecessary. From the account previously given of the performance of Cuthbertson's, and of the other pumps described, as well as from his own experience, he is of opinion that the action of the best air pump is stopped, either by the formation of elastic vapour from the oil necessarily present, or from some unknown property of the air itself, long before it has been so much rarefied as as to be unable to open the piston valves. His reason for this opinion is, that the capacity of the barrels of any well-constructed pump is several thousand times greater than the space which exists between the valves, when the piston has reached the bottom of the barrel; in short, this may be limited to the small hole S N. For example, in an air-pump, the length of the stroke of which is 12 inches, the diameter of the barrels $2\frac{1}{2}$ in. the diameter of the hole S N $\frac{1}{10}$th of an inch, and its length one inch, the capacity of the hole S N is 7500 times less than the capacity of the barrel, and consequently air 7500 times rarer than the atmosphere when filling the whole barrel, will, by the descent of the piston, become of the same density, but as it is known from the performance of Hook's pump, that air $\frac{1}{100}$th part of the density of the atmosphere has sufficient elastic force to open an oil silk valve, it follows that the pump we have supposed, will exhaust 7425 times, but as this degree of exhaustion has nev er yet been attained, it is evident that some other reason must be sought for in explanation of this, than the imperfection of the mechanical arrangement. A metallic valve T *p*, may be placed in the piston instead of the oiled silk one, having a projecting point *p* to open it, on the piston reaching the bottom of the barrel, and a space OT filled with oil, to prevent the return of the air during the time which elapses betwixt the commencement of the ascent of the piston and the complete shutting of the valve.

Fig. 1.

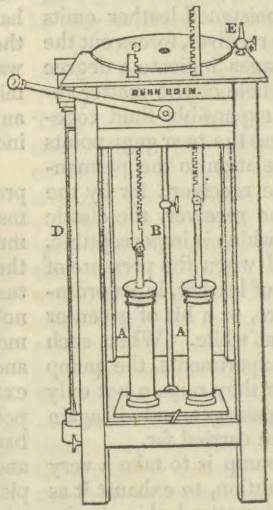


Fig. 2.

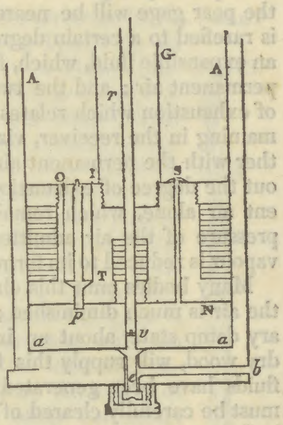


same change that is indicated by $\frac{1}{10}$ of an inch of an ordinary barometer. But a vessel of this size will load a balance too much to leave it sufficiently sensible to small changes of density. Besides, it is affected by heat and cold, and would require a very troublesome equation to correct their effects.

It may perhaps be worth while to attend to this in buying and selling precious commodities; such as pearls, diamonds, silk, and some drugs. As they are generally sold by brass or leaden weights, the buyer will have some advantage when the air is heavy and the barometer high. On the other hand, he will have the advantage in buying gold and mercury when the air is light. It is needless to confine this observation to precious commodities, for the advantage is the same in all in proportion to their levity.

There is a case in which this observation is of consequence to the philosopher: we mean the measuring of time by pendulums. As the accelerating force on a pendulum is not its whole weight, but the excess of its weight over that of the displaced air, it follows that a pendulum will vibrate more slowly in the air than *in vacuo*. A pendulum composed of lead, iron, and brass, may be about 8400 times heavier than the air which it displaces when the barometer is at 30 inches and the thermometer is at 32°, and the accelerating force will be diminished about $\frac{1}{8400}$. This will cause a second pendulum to make about five vibrations less in a day than it would do *in vacuo*. In order therefore to deduce the accelerative power of gravity from the length of a pendulum vibrating in the air, we must make an allowance of 0″.17, or $\frac{17}{100}$ of a second per day, for every inch that the barometer stands lower than 30 inches. But we must also note the temperature of the air; because when the air is warm it is less dense when supporting by its elasticity the same weight of atmosphere, and we must know how much its density is diminished by an increase of temperature. The correction is still more complicated; for the change of density affects the resistance of the air, and this affects the time of the vibration, and this by a law that is not yet well ascertained. As far as we can determine from any experiments that have been made, it appears that the change arising from the altered resistance takes off about 2-5ths of the change produced by the altered density, and that a second pendulum makes but three vibrations a-day more *in vacuo* than in the open air. This is a very unexpected result; but it must be owned that the experiments have neither been numerous nor very nicely made.

The air-pump also allows us to shew the effects of the air's pressure in a great number of amusing and instructive phenomena.

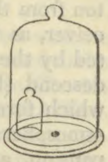
Experiments to shew the effects of the pressure of the air.

When the air is abstracted from the receiver, it is strongly pressed to the pump-plate by the incumbent atmosphere, and it supports this great pressure in consequence of its circular form. Being equally compressed on all sides, there is no place where it should give way rather than another; but if it be thin, and not very round, which is sometimes the case, it will be crushed to pieces. If we take a square thin vial, and apply an exhausting syringe to its mouth, it will not fail being crushed.

As the operation of pumping is something like sucking, many of these phenomena are in common discourse ascribed to suction, a word much abused; and this abuse misleads the mind exceedingly in its contemplation of natural phenomena. Nothing is more usual than to speak of the suction of a syringe, the suction and draught of a chimney, &c. The following experiment puts the true cause of the strong adhesion of the receiver beyond a doubt.

Place a small receiver, or cupping-glass on the pump-plate without covering the central hole, as represented in fig. 47, and cover it with a larger receiver. Exhaust the air from it; then admit it as suddenly as possible. The outer receiver, which, after the rarefaction, adhered strongly to the plate, is now loose, and the cupping-glass will be found sticking fast to it. While the rarefaction was going on, the air in the small receiver also expanded, escaped from it, and was abstracted by the pump. When the external air was suddenly admitted, it pressed on the small receiver, and forced it down to the plate, and thus shut up all entry. The small receiver must now adhere; and there can be no suction, for the pipe of the pump was on the outside of the cupping-glass.

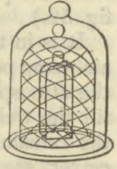
Fig 47.



This experiment sometimes does not succeed, because the air occasionally finds a passage under the brim of the cupping-glass. But if the cupping-glass be pressed down by the hand on the greasy leather or plate, every thing will be made smooth, and the glass will be so little raised by the expansion of its air during the pumping, that it will instantly clap close when the air is re-admitted.

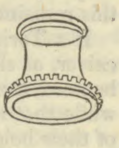
In like manner, if a thin square phial be furnished with a valve, opening from within, but shutting when pressed from without, and if this phial be put under a receiver, and the air be abstracted from the receiver, the air in the phial will expand during the rarefaction, escape through the valve, and be at last in a very rarefied state within the phial. If the air be now admitted into the receiver, it will press on the flat sides of the included phial and crush it to pieces. (See fig. 48.)

Fig. 48.



If a piece of wet ox-bladder be laid over the top of a receiver whose orifice is about four inches wide, and the air be exhausted from within it, the incumbent atmosphere will press down the bladder into a hollow form, and then burst it inward with a prodigious noise. (See fig. 49.) Or if a piece of thin flat glass be laid over the receiver, with an oiled leather between them to make the juncture air-tight, the glass will be broken downwards. This must be done with caution, because the pieces of glass sometimes fly about with great force.[1]

Fig. 49.



If there be formed two hemispherical cups of brass, with very flat thick brims, and one of them be fitted with a neck and stopcock, as represented by fig. 50, the air may be abstracted from them by screwing the neck into the hole in the pump-plate. To prevent the insinuation of air, a ring of oiled leather may be put between the rims. Now unscrew the sphere from the pump, and fix hooks to each, and suspend them from a strong nail, and hang a scale to the lowest. It will require a considerable weight to separate them; namely, about 15 pounds for every square inch of the great circle of the sphere. If this be four inches diameter, it will require near 190 pounds. This pretty experiment was first made by Otto Guericke, and on a very great scale. His sphere was of a large size, and when exhausted, the hemispheres could not be drawn asunder by 20 horses. It was exhibited, along with many others equally curious and magnificent, to the emperor of

Fig. 50.

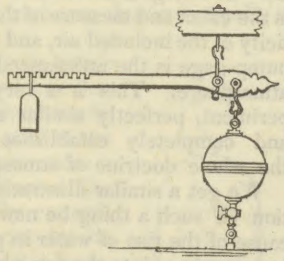


Fig. 51.

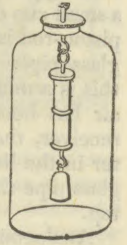


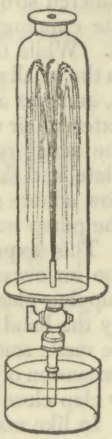
---

[1] Such experiments should never be performed with a good pump; for fragments of the glass will get into the pump and impair its working, in spite of the utmost skill of the operator.

Experiments on air.

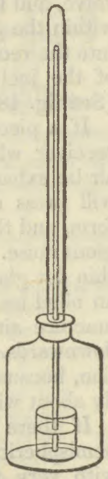
Germany and his court, at the breaking up of the diet of Ratisbon in 1654. If a loaded syringe be suspended by its piston from the hook in the top plate of the receiver, as in fig. 51, and the air be abstracted by the pump, the syringe will gradually descend (because the elasticity of the air, which formerly balanced the pressure of the atmosphere, is now diminished by its expansion, and is therefore no longer able to press the syringe to the piston), and it will at last drop off. If the air be admitted before this happens, the syringe will immediately rise again.

Fig. 52.



Screw a short brass pipe into the neck of a transporter, on which is set a tall receiver, and immerse it into a cistern of water. On opening the cock, the pressure of the air on the surface of the water in the cistern will force it up through the pipe, and cause it to spout into the receiver with a strong jet, because there is no air within to balance by its elasticity the pressure of the atmosphere. (See fig. 52.)

Fig. 53.

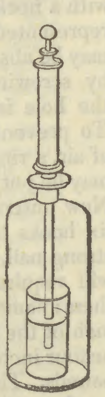


By this pressure the gage of an air-pump acts.

It is in the same way that the gage of the air-pump performs its office. The pressure of the atmosphere raises the mercury in the gage till the weight of the mercury, together with the remaining elasticity of the air in the receiver, are in equilibrio with the whole pressure of the atmosphere: therefore the height and weight of the mercury in the gage is the excess of the weight of the atmosphere above the elasticity of the included air; and the deficiency of this height from that of the mercury in the Toricellian tube is the measure of this remaining elasticity.

If a Toricellian tube be put under a tall receiver, as shown in fig. 53, and the air be exhausted, the mercury in the tube will descend, while that in the gage will rise; and the sum of their heights will always be the same, that is, equal to the height in an ordinary barometer. The height of the mercury in the receiver is the effect and measure of the remaining elasticity of the included air, and the height in the pump-gage is the unbalanced pressure of the atmosphere. This is a very instructive experiment, perfectly similar to Mr. Auzout's, and completely establishes and illustrates the whole doctrine of atmospheric pressure.

Fig. 54.



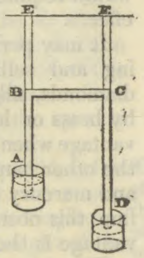
Water rises in pumps.

We get a similar illustration and confirmation (if such a thing be now needed) of the cause of the rise of water in pumps, by screwing a syringe into the top plate of a receiver, which syringe has a glass pipe plunging into a small cup of water. (See fig. 54.) When the piston-rod is drawn up, the water rises in the glass pipe, as in any other pump, of which this is a miniature representation. But if the air has been previously exhausted from the receiver, there is nothing to press on the water in the little jar; and it will not rise in the glass pipe though the piston of the syringe be drawn to the top.

It moves in syphons.

Analogous to the rise of water in pumps is its rise and motion in syphons. Suppose a pipe ABCD, fig. 55, bent at right angles at B and C, and having its two ends immersed in the cisterns of water A and D. Let the leg CD be longer than the leg BA, and let the whole be full of water. The water is pressed upwards at A with a force equal to the weight of the column of air EA reaching to the top of the atmosphere; but it is pressed downwards by the weight of the column of water BA. The water at D is pressed downwards by the weight of the column CD, and upwards by the weight of the column of air FD reaching to the top of the atmosphere. The two columns of air differ very little in their weight, and may without any sensible error be considered as equal. Therefore there is a superiority of pressure downwards at D, and the water will flow out there. The pressure of the air will raise the water in the leg AB, and thus the stream will be kept up till the vessel A is emptied as low as the orifice of the leg BA, provided that the height of AB is not greater than what the pressure of the atmosphere can balance, that is, does not exceed 32 or 33 feet for water, 30 inches for mercury, &c.

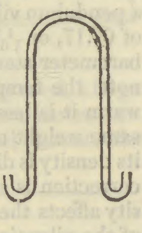
Fig. 55.



A syphon then will always run from that vessel whose surface is highest; the form of the pipe is indifferent, because the hydrostatical pressures depend on the vertical height only. It must be filled with water by some other contrivance, such as a funnel, or a pump applied a-top; and the funnel must be stopped up, otherwise the air would get in, and the water would fall in both legs.

If the syphon have equal legs, and be turned up at the ends, it will remain full of water, and be ready for use. One end of it need only be dipped into any vessel of water, and the water will then flow out at the other end of the syphon. This is called the Wirtemberg syphon, and is represented in fig. 56.

Fig. 56.

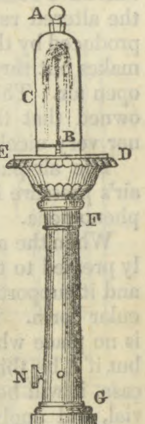


The syphon fou tain.

What is called the *syphon fountain*, constructed on this principle, is shown in fig. 57, where AB is a tall receiver, standing in a wide bason DE, which is supported on the pedestal H, by the hollow pillar FG. In the centre of the receiver is a jet pipe C, and in the top a ground stopper A. Near the base of the pillar is a cock N, and in the pedestal is another cock O.

Fill the bason DE with water within half an inch of the brim. Then pour in water at the top of the receiver (the cock N being shut) till it is about half full, and then put in the stopper. A little water will run out into the vessel DE. But before it runs over, open the cock N, and the water will run into the cistern H; and by the time that the pipe C appears above water, a jet will rise from it, and continue as long as water is supplied from the bason DE. The passage into the base cistern may be so tempered by the cock N that the water within the receiver shall keep at the same height, and what runs into the base may be received from the cock O into another vessel, and returned into DE, to keep up the stream.

Fig. 57.



Manner of its construction and operation.

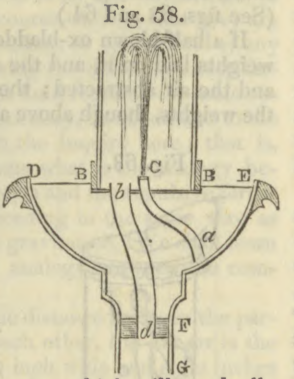
This pretty philosophical toy may be constructed in the following manner. BB, (fig. 58,) is the ferril or cap into which the receiver is cemented. From its centre descends the jet pipe C*a*, sloping outwards, to give room for the discharge pipe *bd* of larger diameter, the lower extremity of which *d* fits tightly into the top of the hollow pillar FG.

The operation of the toy is easily understood. Suppose the distance from C to H (fig. 57,) three feet, which is about $\frac{1}{11}$ of the height at which the atmosphere would support a column of water. The water poured into AB would descend through FG (the hole A being shut) till the air has

Experiments on air.

expanded $\frac{1}{15}$, and then it would stop. If the pipe C*a* be now opened, the pressure of the air on the surface of the water in the cistern DE will cause it to spout through C to the height of three feet nearly, and the water will continue to descend through the pipe FG. By tempering the cock N so as to allow the water to pass through it as fast as it is supplied by the jet, the amusement may be continued a long time. It will stop at last, however; because, as the jet is made into rarefied air, a little air will be extricated from the water, which will gradually accumulate in the receiver, and diminish its rarefaction, which is the moving cause of the jet. This indeed is an inconvenience felt in every employment of syphons, so much the more remarkably as their top is higher than the surface of the water in the cistern of supply.

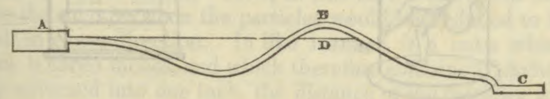
Fig. 58.



Syphons tare ofen used thus.

Cases of this employment of a syphon are not unfrequent. When water collected at A (fig. 59,) is to be conducted in a pipe to C, situated in a lower part of the country, it sometimes happens that the intervening ground is higher than the fountain-head as at B. A forcing pump is erected at A, and the water forced along the pipe. Once it runs out at C, the pump may be removed, and the water will continue to run on the syphon principle, provided BD do not exceed 33 feet. But the water in that part of the conduit which is above the horizontal plane AD, is in the same state as in a receiver of rarefied air, and gives out some of the air which is united with it. This gradually accumulates in the elevated part of the conduit, and at last choaks it entirely.

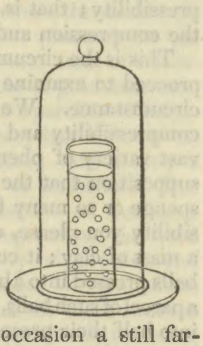
Fig. 59.



The air-pump discovers the combination of air with water, &c.

This combination of air with water is very distinctly seen by means of the air-pump. If a small glass containing cold water, fresh drawn from the spring, be exposed, as in fig. 60, under the receiver, and the air rarefied, small bubbles will be observed to form on the inner surface of the glass, or on the surface of any body immersed in it, which will increase in size, and then detach themselves from the glass and reach the top; as the rarefaction advances, the whole water begins to show very minute air-bubbles rising to the top; and this appearance will continue for a very long time, till it be completely disengaged. Warming the water will occasion a still farther separation of air, and a boiling heat will separate all that can be disengaged. The reason assigned for these air-bubbles first appearing on the surface of the glass, &c. is, that air is attracted by bodies, and adheres to their surface. This may be so. But it is more probably owing to the attraction of the water for the glass, which causes it to quit the air which it held in solution, in the same manner as we see it happen when it is mixed with spirits-of-wine, with vitriolic acid, &c., or when salts or sugar are dissolved in it. For if we pour out the water which has been purged of air by boiling *in vacuo*, and fill the glass with fresh water, we shall observe the same thing, although a film of the purified water was left adhering to the glass. In this case there can be no air adhering to the glass.

Fig. 60.



Experiments on air.

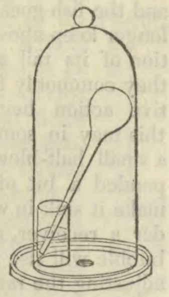
Water thus purged of air by boiling (or even without boiling) *in vacuo*, will again absorb air when exposed to the atmosphere. The best demonstration of this is to fill with this water a phial, leaving about the size of a pea not filled. Immerse this in a vessel of water, with the mouth undermost, by which means the air-bubble will mount up to the bottom of the phial. After some days standing in this condition, the air-bubble will be completely absorbed, and the vessel quite filled with water. A glass of beer placed under the receiver and treated in the same way will be almost wholly converted into froth by the escape of its fixed air, and will have lost entirely the prickling smartness which is so agreeable, and become quite vapid.

Experiments illustrative of the elasticity and expansibility of the air.

The air-pump gives us, in the next place, a great variety of experiments illustrative of the air's elasticity and expansibility. The very operation of exhaustion, as it is called, is an instance of its great expansibility. But this is not palpably exhibited to view. The following experiments show it most distinctly. First, put a flaccid bladder, of which the neck is firmly tied with a thread, under a receiver, and work the pump. The bladder will gradually swell, and will even be fully distended. Upon readmitting the air into the receiver, the bladder gradually collapses again into its former dimensions; while the bladder is flaccid, the air within it is of the same density and elasticity with the surrounding air, and its elasticity balances the pressure of the atmosphere. When part of the air of the receiver is abstracted, the remainder expands so as still to fill the receiver; but by expanding, its elasticity is plainly diminished; for we see by the fact, that the elasticity of the air of the receiver no longer balances the elasticity of that in the bladder, as it no longer keeps it in its dimensions. The air in the bladder expands also; it expands till its diminished elasticity is again *in equilibrio* with the diminished elasticity of the air in the receiver; that is, till its density is the same. When all the wrinkles of the bladder have disappeared, its air can expand no more, although we continue to diminish the elasticity of the air of the receiver by further rarefaction. The bladder now tends to burst; and if it be pierced by a point or knife fastened to the slip-wire, the air will rush out, and the mercury descend rapidly in the gage.

If a phial or tube (fig. 61) be partly filled with water, and immersed in a vessel of water with the mouth downwards, the air will occupy the upper part of the phial. If this apparatus be put under a receiver, and the air be abstracted, the air in the phial will gradually expand, allowing the water to run out by its weight till the surface of the water be on a level within and without. When this is the case, we must grant that the density and elasticity of the air in the phial is the same with that in the receiver. When we work the pump again, we shall observe the air in the phial expand still more, and come out of the water in bubbles. Continuing the operation, we shall see the air continually escaping from the phial; when this is over, it shows that the pump can rarefy no more. If we now admit the air into the receiver, we shall see the water rise into the phial, and at last almost completely fill it, leaving only a very small bubble of air at the top. This bubble had expanded so as to fill the whole phial.

Fig. 61.



Every one must have observed a cavity at the big end of an egg between the shell and the white. The white and

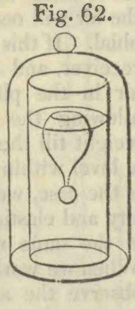
Experiments on air.

yolk are contained in a thin membrane or bladder which adheres loosely to the shell, but is detached from it at that part; and this cavity increases by keeping the egg in a dry place. One may form a judgment of its size, and therefore of the freshness of the egg, by touching it with the tongue; for the shell, where it is not in contact with the contents, will presently feel warm, being quickly heated by the tongue, whilst the rest of the egg will feel cold.

If a hole be made in the opposite end of the egg, and it be set on a little tripod, and put under a receiver, the expansion of the air in the cavity of the egg will force the contents through the hole till the egg be quite emptied; or, if nearly one-half of the egg be taken away at the other end, and the white and yolk taken out, and the shell be put under a receiver, and the air abstracted, the air in the cavity of the egg will expand, gradually detaching the membrane from the shell, till it causes it to swell out, and gives the whole the appearance of an entire egg. In like manner shrivelled apples and other fruits will swell in vacuo by the expansion of the air confined in their cavities.

If a piece of wood, a twig with green leaves, charcoal, plaster of Paris, &c. be kept under water in vacuo, a prodigious quantity of air will be extracted; and if we readmit the air into the receiver, it will force the water into the pores of the body. In this case the body will not swim in water as it did before, showing that the vegetable fibres are specifically heavier than water. It is found, however, that the air contained in the pith and bark, such as cork, is not all extricated in this way; and that much of it is contained in vesicles which have no outlet; being secreted into them in the process of vegetation, as it is secreted in the air-bladder of fishes, where it is generally found in a pretty compressed state, considerably denser than the surrounding air. The air-bladder of a fish is surrounded by circular and longitudinal muscles, by which the fish can compress the air still further; and, by ceasing to act with them, allow it to swell out again. It is in this manner that the fish can suit its specific gravity to its situation in the water, so as to have no tendency either to rise or sink; but if the fish be put into the receiver of an air-pump, the rarefaction of the air obliges the fish to act more strongly with these contracting muscles, in order to adjust its specific gravity; and if too much air has been abstracted from the receiver, the fish is no longer able to keep its air-bladder in the proper degree of compression. It becomes therefore too buoyant, and comes to the top of the water, and is obliged to struggle with its tail and fins in order to get down; frequently in vain. The air-bladder sometimes bursts, and the fish goes to the bottom, and can no longer keep above without the continual action of its tail and fins. When fishes die, they commonly float at top, their contractive action being now at an end. All this may in some degree be illustrated by a small half-blown bladder, to which is appended a bit of lead, just so heavy as to make it sink in water; when this is put under a receiver, and the air abstracted, the bubble will rise to the top; and, by nicely adjusting the rarefaction, it may be kept at any height.

Fig. 62.



The playthings called *Cartesian devils* are similar to this. They are hollow glass figures, having a small aperture in the lower part of the figures, as at the point of the foot; their weight is adjusted so that they swim upright in water. When put into a tall jar filled to the top, and having a piece of leather tied over it, they will sink in the water, by pressing on the leather with the ball of the hand. This, by compressing the water, forces some of it to enter into the figure, and makes it heavier than the water; for which reason it sinks, but rises again on removing the pressure of the hand. (See figs. 63 and 64.)

Experiments on air.

If a half-blown ox-bladder be put into a box, and great weights laid on it, and the whole be put under a receiver, and the air abstracted; the air will, by expanding, lift up the weights, though above an hundred pounds. (See fig. 65.)

Fig. 63.

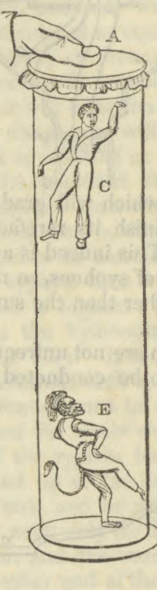


Fig. 64.

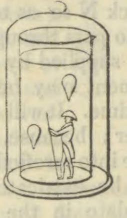

Fig. 65.

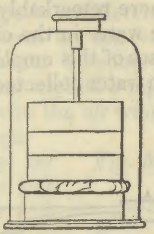


Compressibility and expansibility are in no state of the air very dissimilar.

By such experiments, the great expansibility of the air is abundantly illustrated, as its compressibility was formerly by means of the condensing syringe. We now see that the two sets of experiments form an uninterrupted chain; and that there is no particular state of the air's density where the compressibility and expansibility are remarkably dissimilar. Air in its ordinary state expands; because its ordinary state is a state of compression by the weight of the atmosphere; and if there were a pit about thirty-three miles deep, the air at the bottom would probably be as dense as water; and if it were fifty miles deep, it would be as dense as gold, if it did not become a liquid before this depth; nay, if a bottle with its mouth undermost were immersed six miles under water, it would probably be as dense as water; we say probably, for this depends on the nature of its compressibility; that is, on the relation which subsists between the compression and the force which produces it.

Relation between compression and the force producing it.

This is the circumstance of its constitution, which we now proceed to examine; and it is evidently a very important circumstance. We have long ago observed, that the great compressibility and permanent fluidity of air, observed in a vast variety of phenomena, is totally inexplicable, on the supposition that the particles of air are like so many balls of sponge or so many foot-balls. Give to those what compressibility you please, common air could no more be fluid than a mass of clay; it could no more be fluid than a mass of such balls pressed into a box. It may be demonstrated, that before a parcel of such balls, just touching each other, can be squeezed into half their present dimensions, their globular shape will be entirely gone, and each will have become a perfect cube, touching six other cubes with its whole surface; and these cubes will be strongly compressed together, so that motion could never be performed through among them by any solid body without a very great force. Whereas we know that in this state air is just as permeable to every body as the common air that we breathe. There is no way in which we can represent this fluidity to our imagination, but by conceiving air to consist of particles, not only discrete, but distant from each other, and actuated by repulsive forces, or

Experiments on air.

something analogous to them. It is an idle subterfuge, to which some naturalists have recourse, saying, that they are kept asunder by an intervening ether, or elastic fluid of any other name. This is only removing the difficulty a step farther off; for the elasticity of this fluid requires the same explanation; and therefore it is necessary, in obedience to the rules of just reasoning, to begin the inquiry here; that is, to determine from the phenomena what is the analogy between the distances of the particles and the repulsive forces exerted at these distances, proceeding in the same way as in the examination of planetary gravitation. We shall learn the analogy by attending to the analogy between the compressing force and the density.

Density explained as applied to air.

For the density depends on the distance between the particles; the nearer they are to each other, the denser is the air. Suppose a square pipe one inch wide and eight inches long, shut at one end, and filled with common air; then suppose a plug so nicely fitted to this pipe that no air can pass by its sides; suppose this piston thrust down to within an inch of the bottom: it is evident that the air which formerly filled the whole pipe now occupies the space of one cubic inch, which contains the same number of particles as were formerly diffused over eight cubic inches.

The condensation would have been the same if the air which fills a cube whose side is two inches had been squeezed into a cube of one inch, for the cube of two inches also contains eight inches. Now, in this case it is evident that the distance between the particles would be reduced to its half in every direction. In like manner, if a cube whose side is three inches, and which therefore contains 27 inches, be squeezed into one inch, the distance of the particles will be one-third of what it was: in general the distance of the particles will be as the cube-root of the space into which they are compressed. If the space be $\frac{1}{8}$, $\frac{1}{27}$, $\frac{1}{64}$, $\frac{1}{125}$, &c. of its former dimensions, the distance of the particles will be $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c. Now the term *density*, in its strict sense, expresses the vicinity of the particles; thus, *densi arbores* are trees growing near each other. The measure of this vicinity therefore is the true measure of the density; and when 27 inches of air are compressed into one, we should say that it is three times as dense; but we say, that it is 27 times denser.

Further explanation.

Density is therefore used in a sense different from its strictest acceptation; it expresses the comparative number of equidistant particles contained in the same bulk. This is also abundantly precise, when we compare bodies of the same kind, differing in density only; but we also say, that gold is 19 times denser than water, because the same bulk of it is 19 times heavier. This assertion proceeds on the assumption, or the fact, that every ultimate atom of terrestrial matter is equally heavy. A particle of gold may contain more or fewer atoms of matter than a particle of water. In such a case, therefore, the term density has little or no reference to the vicinity of the particles; and is only a term of comparison of other qualities or accidents. But when we speak of the respective densities of the same substance in its different states of compression, the word *density* is strictly connected with vicinity of particles, and we may safely take either of the measures. We shall abide by the common acceptation, and call that air eight times as dense which has eight times as many particles in the same bulk, although the particles are only twice as near to each other.

Analogy.

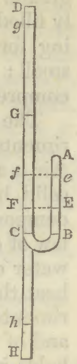
Thus then we see, that by observing the analogy between the compressing force and the density, we shall discover the analogy between the compressing force and the distance of the particles. Now the force which is necessary for compressing two particles of air to a certain vicinity is a proper measure of the elasticity of the particles corresponding to that vicinity or distance; for it balances it, and forces which balance must be esteemed equal. Elasticity is a distinctive name for that corpuscular force which keeps the particles at that distance; therefore observations made on the analogy between the compressing force and the density of air will give us the law of its corpuscular force, in the same way that observations on the simultaneous deflections of the planets towards the sun gives us the law of celestial gravitation.

But the sensible compressing forces which we are able to apply is at once exerted on unknown thousands of particles, whilst it is the law of action of a single particle that we want to discover. We must therefore know the proportion of the numbers of particles on which the compressing force is exerted. It is easy to see, that since the distance of the particles is as the cube root of the density inversely, the number of particles in physical contact with the compressing surface must be as the square of this root. Thus, when a cube of eight inches is compressed into one inch, and the particles are twice as near each other as they were before, there must be four times the number of particles in contact with each of the sides of this cubical inch; or, when we have pushed down the square piston of the pipe spoken of above to within an inch of the bottom, there will be four times the number of particles *immediately* contiguous to the piston, and resisting the compression; and in order to obtain the force really exerted on one particle, and the elasticity of that particle, we must divide the whole compressing force by 4. In like manner, if we have compressed air into $\frac{1}{27}$th of its former bulk, and brought the particles into $\frac{1}{3}$d of their former distance, we must divide the compressing force by 9. In general, if d express the density, $\frac{1}{\sqrt[3]{d}}$ will express the distance x of the particles; $\sqrt[3]{d}$, or $d^{\frac{1}{3}}$ will express the vicinity or real density; and $d^{\frac{2}{3}}$ will express the number of particles acting on the compressing surface; and if f express the accumulated external compressing force, $\frac{f}{d^{\frac{2}{3}}}$ will express the force acting on one particle; and therefore the elasticity of that particle corresponding to the distance x.

Compressibility of air.

We now proceed to consider the experiments by which the law of compression is to be established.[1] In order to examine the compressibility of air that is not rarer than the atmosphere at the surface of the earth, we employ a bent tube or syphon ABCD (fig. 66), hermetically sealed at A, and open at D. The short leg AB must be very accurately divided in the proportion of its solid contents, and fitted with a scale whose units denote equal increments, not of length, but of capacity. There are various ways of doing this; but it requires the most scrupulous attention, and without this the experiments are of no value. In particular, the arched form at A must be noticed. A small quantity of mercury must then be poured into the tube, and passed backwards and forwards till it stands (the tube being held in a vertical position) on a level at B and C. Then we are certain that the included air is of the same density with that of the contiguous atmosphere. Mercury is now poured into the leg DC, which will fill it,

Fig. 66.



---

[1] The first experiments to this purpose were those made by Mr. Boyle, published in his *Defensio Doctrinæ de Aere contra Linum*, and exhibited before the Royal Society the year before. Mariotte made experiments of the same kind, which were published in 1676 in his *Essai sur la Nature de l'Air*, and *Traité des Mouvemens des Eaux*. The most copious experiments are those by Sulzer (*Mem. Berlin*, ix.) those by Fontana (*Opuscula Physico-Mathematica*), and those by Sir George Shuckburgh and General Roy in the *Philosophical Transactions*.

suppose to G, and will compress the air into a smaller space AE. Draw the horizontal line EF; the new bulk of the compressed air is evidently AE, measured by the adjacent scale, and the addition made to the compressing force of the atmosphere is the weight of the column GF. Produce GF downwards to H, till FH is equal to the height shown by a Toricellian tube filled with the *same mercury;* then the whole compressing force is HG. This is evidently the measure of the elasticity of the compressed air in AE, for it balances it. Now, pour in more mercury, and let it rise to *g*, compressing the air into A *e*. Draw the horizontal line *e f*, and make *f h* equal to FH; then A *e* will be the new bulk of the compressed air, $\frac{AB}{Ae}$ will be its new density, and *h g* will be the measure of the new elasticity. This operation may be extended as far as we please, by lengthening the tube CD, and taking care that it be strong enough to resist the great pressure. Great care must be taken to keep the whole in a constant temperature, because the elasticity of air is greatly affected by heat, and the change by any increase of temperature is different according to its density or compression.

Experiments of Boyle, &c.

The experiments of Boyle, Mariotte, Amontons, and others, were not extended to very great compressions, the density of the air not having been quadrupled in any of them; nor do they seem to have been made with very great nicety. It may be collected from them in general, that the elasticity of the air is very nearly proportioned to its density; and accordingly this law was almost immediately acquiesced in, and was called the *Boylean law;* it is accordingly assumed by almost all writers on the subject as exact. Of late years, however, there occurred questions in which it was of importance that this point should be more scrupulously settled, and the former experiments were repeated and extended. Sulzer and Fontana have carried them farther than any other. Sulzer compressed air into one-eighth of its former dimensions.

Varieties in these experiments.

Considerable varieties and irregularities are to be observed in these experiments. It is extremely difficult to preserve the temperature of the apparatus, particularly of the leg AB, which is most handled. A great quantity of mercury must be employed; and it does not appear that philosophers have been careful to have it precisely similar to that in the barometer, which gives us the unit of compressing force and of elasticity. The mercury in the syphon as well as in the barometer should be pure and boiled. If the mercury in the syphon is adulterated with bismuth and tin, which it commonly is to a considerable degree, the compressing force, and consequently the elasticity, will appear greater than the truth. If the barometer has not been nicely filled, it will be lower than it should be, and the compressing force will appear too great, because the unit is too small; and this error will be most remarkable in the smaller compressions.

Heterogeneous nature of the air.

The greatest source of error and irregularity in the experiments is the very heterogeneous nature of the air itself. Air is a solvent of all fluids, all vapours, and perhaps of many solid bodies. It is highly improbable that the different compounds shall have the same elasticity, or even the same law of elasticity; and it is well known, that air loaded with water or other volatile bodies, is much more expansible by heat than pure air; nay, it would appear from many experiments, that certain determinate changes both of density and of temperature, cause air to let go the vapours which it holds in solution. Cold causes it to precipitate water, as appears in dew; so does rarefaction, as is seen in the receiver of an air-pump.

The elasticity of air.

In general, it appears that the elasticity of air does not increase quite so fast as its density. This will be best seen by the following tables, calculated from the experiments of Mr. Sulzer. The column E in each set of experiments expresses the length of the column GH, the unit being FH, whilst the column D expresses $\frac{AB}{AE}$.

First set.		Second set.		Third set.	
D	E	D	E	D	E
1·000	1·000	1·000	1·000	1·000	1·000
1·100	1·093	1·236	1·224	1·091	1·076
1·222	1·211	1·294	1·288	1·200	1·183
1·375	1·284	1·375	1·332	1·333	1·303
1·571	1·559	1·466	1.417	1·500	1·472
1·692	1·669	1·571	1·515	1·714	1·659
1·833	1·796	1·692	1·647		
2·000	1·958	2·000	1·964	2·000	1·900
2·288	2·130				
2·444	2·375	2·444	2·392	2·400	2·241
3·143	2·936	3·143	3·078	3·000	2·793
3·666	3·391	3·666	3·575		
4·000	3·706			4·000	3·631
4·444	4·035	4·444	4·320		
4·888	4·438				
5·500	4·922	5·500	5·096		
5·882	5·522			6·000	5·297
		7·333	6·694		
				8·000	6·835

There appears in these experiments to be sufficient grounds for calling in question the Boylean law; and the writer of this article thought it incumbent on him to repeat them with some precautions, which probably had not been attended to by Mr. Sulzer. He was particularly anxious to have the air as free as possible from moisture. For this purpose, having detached the short leg of the syphon, which was 34 inches long, he boiled mercury in it, and filled it with mercury boiling hot. He took a tinplate vessel of sufficient capacity, and put into it a quantity of powdered quicklime just taken from the kiln; and having closed the mouth, he agitated the lime through the air in the vessel, and allowed it to remain there all night. He then emptied the mercury out of the syphon into this vessel, keeping the open end far within it. By this means the short leg of the syphon was filled with very dry air. The other part was now joined, and boiled mercury put into the bend of the syphon; and the experiment was then prosecuted with mercury which had been recently boiled, and was the same with which the barometer had been carefully filled.

The results of the experiments are expressed in the following table:

First set.		Second set.		Third set.	
D	E	D	E	D	E
1·000	1·000	1·000	1·000	1·000	1·000
2·000	1·957	2·000	1·920	2·000	1·909
3·000	2·848	3·000	3·839	3·000	2·845
4·000	3·737	4·000	3·726	4·000	3·718
5·500	4·930	5·500	5·000	5·500	5·104
6·000	5·342	6·000	5·452	6·000	5·463
7·620	6·490	7·620	6·775	7·620	6·812

Here it appears again in the clearest manner that the elasticities do not increase as fast as the densities, and the differences are even greater than in Mr. Sulzer's experiments.

The second table contains the results of experiments which were made on very damp air in a warm summer's morning. In these it appears that the elasticities are almost precisely proportional to the densities + a small constant quantity, nearly 0·11, deviating from this rule chiefly between the densities 1 and 1·5, within which limits we have very nearly $D = E^{1\cdot0017}$. As this air is nearer to the constitution of atmospheric air than the former, this rule may be safely followed in cases where atmospheric air is concerned, as in measuring the depths of pits by the barometer.

The third table shows the compression and elasticity of air strongly impregnated with the vapours of camphire. Here the Boylean law appears pretty exact, or rather the elasticity seems to increase a little faster than the density.

Dr. Hooke examined the compression of air by immersing a bottle to great depths in the sea, and weighing the water which got into it without any escape of air. But this method was liable to great uncertainty, on account of the unknown temperature of the sea at great depths.

Mode of examining the elasticity of rarefied air.

Hitherto we have considered only such air as is not rarer than what we breathe; we must take a very different method for examining the elasticity of rarefied air. Let *gh* (fig. 67,) be a long tube, formed a-top into a cup, and of sufficient diameter to receive another smaller tube *af*, open at first at both ends. Let the outer tube and cup be filled with mercury, which will rise in the inner tube to the same level. Let *af* now be stopped at *a*. It contains air of the same density and elasticity with the adjoining atmosphere. Note exactly the space *ab* which it occupies. Draw it up into the position of fig. 68, and let the mercury stand in it at the height *de*, whilst *ce* is the height of the mercury in the barometer. It is evident that the column *d e* is in equilibrio between the pressure of the atmosphere and the elasticity of the air included in the space *a d*. And since the weight of *c e* would be in equilibrio with the whole pressure of the atmosphere, the weight of *c d* is equivalent to the elasticity of the included air. Whilst therefore *c c* is the measure of the elasticity of the surrounding atmosphere, *c d* will be the measure of the elasticity of the included air; and since the air originally occupied the space *a b*, and has now expanded into *a d*, we have $\frac{ab}{ad}$ for the measure of its density. N.B. *c e* and *c d* are measured by the *perpendicular heights* of the columns, but *a b* and *a d* must be measured by their *solid capacities*.

By raising the inner tube still higher, the mercury will also rise higher, and the included air will expand still farther, and we obtain another *c d*, and another $\frac{ab}{ad}$; and in this manner the relation between the density and elasticity of rarefied air may be discovered.

Fig. 67.

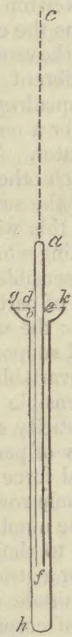


Fig. 68.

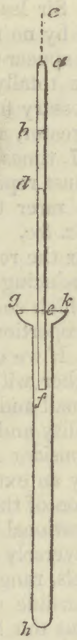

Fig. 69.

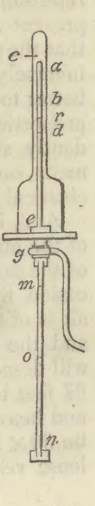


An easier method.

This examination may be managed more easily by means of the air-pump. Suppose a tube *ae* (fig. 69) containing a small quantity of air *a b*, set up in a cistern of mercury, which is supported in the tube at the height *e b*, and let *e c* be the height of the mercury in the barometer. Let this apparatus be set under a tubulated receiver on the pump-plate, and let *g n* be the pump-gage, and *m n* be made equal to *c e*.

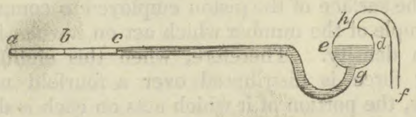
Then, as has been already shown, *c b* is the measure of the elasticity of the air in *a b*, corresponding to the bulk *a b*. Now let some air be abstracted from the receiver. The elasticity of the remainder will be diminished by its expansion; and therefore the mercury in the tube *a e* will descend to some point *d*. For the same reason, the mercury in the gage will rise to some point *o*, and *m o* will express the elasticity of the air in the receiver. This would support the mercury in the tube *a e* at the height *e r*, if the space *a r* were entirely void of air. Therefore *r d* is the effect and measure of the elasticity of the included air when it has expanded to the bulk *a d;* and thus its elasticity, under a variety of other bulks, may be compared with its elasticity when of the bulk *a b*. When the air has been so far abstracted from the receiver that the mercury in *a e* descends to *e*, then *m o* will be the precise measure of its elasticity.

In all these cases it is necessary to compare its bulk *a b* with its natural bulk, in which its elasticity balances the pressure of the atmosphere. This may be done by laying the tube *a c* horizontally, and then the air will collapse into its ordinary bulk.

Another method.

Another easy method may be taken for this examination. Let an apparatus *a b c d e f* (fig. 70,) be made, consisting of a horizontal tube *a e* of even bore, a ball *d g e* of a large diameter, and a swan-neck tube *h f*. Let the ball and part of the tube *g e b* be filled with mercury, so that the tube may be in the same horizontal plane with the surface *d e* of the mercury in the ball. Then seal up the end *a*, and connect *f* with an air-pump. When the air is abstracted from the surface *d e*, the air in *a b* will expand into a larger bulk *a c*, and the mercury in the pump-gage will rise to some distance below the barometric height. It is evident that this distance, without any farther calculation, will be the measure of the elasticity of the air pressing on the surface *d e*, and therefore of the air in *a e*.

Fig. 70.



The most exact mode.

The most exact of all methods is to suspend in the receiver of an air-pump a glass vessel, having a very narrow mouth, over a cistern of mercury, and then abstract the air till the gage rises to some determined height. The difference *e* between this height and the barometric height determines the elasticity of the air in the receiver and in the suspended vessel. Now, lower down that vessel by the slip-wire till its mouth is immersed into the mercury, and admit the air into the receiver; it will press the mercury into the little vessel. Lower it still further down, till the mercury within it is level with that without; then stop its mouth, take it out and weigh the mercury, and let its weight be *w*. Subtract this weight from the weight *v* of the mercury, which would completely fill the whole vessel; then the natural bulk of the air will be *v—w*, whilst its bulk, when of the elasticity *e* in the rarefied receiver, was the bulk or capacity *w* of the vessel. Its density therefore, corresponding to this elasticity *e*, was $\frac{v-w}{w}$. And thus may the relation between density and elasticity in all cases be obtained.

Various experiments made to this purpose.

A great variety of experiments to this purpose have been made, with different degrees of attention, according to the interest which the philosophers had in the result. Those made by M. de Luc, General Roy, Mr. Trembley, and Sir George Shuckburgh, are by far the most accurate; but they are all confined to very moderate rarefactions. The gene-

Boylean Law.

ral result has been, that the elasticity of rarefied air is very nearly proportional to its density. We cannot say with confidence that any regular deviation from this law has been observed, there being as many observations on one side as on the other; but we think that it is not unworthy the attention of philosophers to determine it with precision in the cases of extreme rarefaction, where the irregularities are most remarkable. The great source of error is a certain adhesive sluggishness of the mercury when the impelling forces are very small; and other fluids can hardly be used, because they either smear the inside of the tube and diminish its capacity, or they are converted into vapour, which alters the law of elasticity.

The Boylean law may be assumed.

Let us, upon the whole, assume the Boylean law, viz. that the elasticity of the air is proportional to its density. The law deviates not in any sensible degree from the truth in those cases which are of the greatest practical importance, that is, when the density does not much exceed or fall short of that of ordinary air.

Investigation.

Let us now see what information this gives us with respect to the action of the particles on each other. The investigation is extremely easy. We have seen that a force eight times greater than the pressure of the atmosphere will compress common air into the eighth part of its common bulk, and give it eight times its common density; and in this case we know, that the particles are at half their former distance, and that the number which are now acting on the surface of the piston employed to compress them is quadruple of the number which act on it when it is of the common density. Therefore, when this eightfold compressing force is distributed over a fourfold number of particles, the portion of it which acts on each is double. In like manner, when a compressing force 27 is employed, the air is compressed into $\frac{1}{27}$ of its former bulk, the particles are at $\frac{1}{3}$ of their former distance, and the force is distributed among 9 times the number of particles; the force on each is therefore 3. In short, let $\frac{1}{x}$ be the distance of the particles, the number of them in any given vessel, and therefore the density will be as x^3, and the number pressing by their elasticity on its whole internal surface will be as x^2. Experiment shews, that the compressing force is as x^3, which being distributed over the number as x^2, will give the force on each as x. Now, this force is in immediate equilibrium with the elasticity of the particle immediately contiguous to the compressing surface. This elasticity is therefore as x; and it follows from the nature of perfect fluidity, that the particle adjoining to the compressing surface presses with an equal force on its adjoining particles on every side. Hence we must conclude, that the corpuscular repulsions exerted by the adjoining particles are inversely as their distances from each other, or that the adjoining particles tend to recede from each other with forces inversely proportional to their distances.

Sir Isaac Newton first reasoned properly.

Sir Isaac Newton was the first who reasoned in this manner from the phenomena. Indeed he was the first who had the patience to reflect on the phenomena with any precision. His discoveries in gravitation naturally gave his thoughts this turn, and he very early hinted his suspicions that all the characteristic phenomena of tangible matter were produced by forces which were exerted by the particles at small and insensible distances. And he considers the phenomena of air as affording an excellent example of this investigation, and deduces from them the law which we have now demonstrated; and says, that air consists of particles which avoid the adjoining particles with forces inversely proportional to their distances from each other. From this he deduces (in the second book of his Principles) several beautiful propositions, determining the mechanical constitution of the atmosphere.

Limits.

But it must be noticed that he limits this action to the *adjoining* particles; and this is a remark of immense consequence, though not attended to by the numerous experimenters who adopt the law.

Height of the atmosphere.

It is plain that the particles are supposed to act at a distance, and that this distance is variable, and that the forces diminish as the distances increase. A very ordinary air-pump will rarefy the air 125 times. The distance of the particles is now 5 times greater than before; and yet they still repel each other; for air of this density will still support the mercury in a syphon-gage at the height of 0·24, or $\frac{24}{100}$ of an inch; and a better pump will allow this air to expand twice as much, and still leave it elastic. Thus we see that whatever is the distance of the particles of common air, they can act five times further off. The question comes now to be, Whether, in the state of common air, they really do act five times further than the distance of the adjoining particles? Whilst the particle *a* acts on the particle *b* with the force 5, does it also act on the particle *c* with the force 2·5, on the particle *d* with the force 1·667, on the particle *e* with the force 1·25, on the particle *f* with the force 1, on the particle *g* with the force 0.833, &c.

Sir Isaac Newton shows in the plainest manner, that this is by no means the case; for if this were the case, he makes it appear that the sensible phenomena of condensation would be totally different from that we observe. The force necessary for a quadruple condensation would be eight times greater, and for a monuple condensation the force must be 27 times greater. Two spheres filled with condensed air must repel each other, and two spheres containing air that is rarer than the surrounding air must attract each other, &c. &c. All this will appear very clearly, by applying to air the reasoning which Sir Isaac Newton has employed in deducing the sensible law of mutual tendency of two spheres, which consist of particles attracting each other with forces proportional to the square of the distance inversely.

If we could suppose that the particles of air repelled each other with invariable forces at all distances within some small and insensible limit, this would produce a compressibility and elasticity similar to what we observe. For if we consider a row of particles, within this limit, as compressed by an external force applied to the two extremities, the action of the whole row on the extreme points would be proportional to the number of particles, that is, to their distance inversely and to their density: and a number of such parcels, ranged in a straight line, would constitute a row of any sensible magnitude having the same law of compression. But this law of corpuscular force is unlike every thing we observe in nature, and to the last degree improbable.

We must therefore continue the limitation of this mutual repulsion of the particles of air, and be contented for the present with having established it as an experimental fact, that the adjoining particles of air are kept asunder by forces inversely proportional to their distances; or perhaps it is better to abide by the sensible law, that the density of air is proportional to the compressing force. This law is abundantly sufficient for explaining all the subordinate phenomena, and for giving us a complete knowledge of the mechanical constitution of our atmosphere.

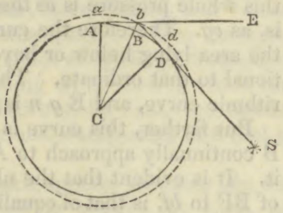
The height of the air investigated.

And, in the first place, this view of the compressibility of the air must give us a very different notion of the height of the atmosphere from what we deduced on a former occasion from our experiments. It is found, that when the air is of the temperature 32° of Fahrenheit's thermometer, and the mercury in the barometer stands at 30 inches, it will descend one-tenth of an inch if we take it to a place 87 feet higher. Therefore, if the air were equally dense and heavy throughout, the height of the atmosphere would be 30 × 10 × 87 feet, or 5 miles and 100 yards. But the loose reasoning adduced on that occasion was enough to

Height of the atmosphere.

show us that it must be much higher; because every stratum as we ascend must be successively rarer as it is less compressed by incumbent weight. Not knowing to what degree air expanded when the compression was diminished, we could not tell the successive diminutions of density and consequent augmentation of bulk and height; we could only say, that several atmospheric appearances indicated a much greater height. Clouds have been seen much higher; but the phenomenon of the twilight is the most convincing proof of this. There is no doubt that the visibility of the sky or air is owing to its want of perfect transparency, each particle, whether of matter purely aerial or heterogeneous, reflecting a little light.

Fig. 71.



Let *b* (fig. 71) be the last particle of illuminated air which can be seen in the horizon by a spectator at A. This must be illuminated by a ray SD *b*, touching the earth's surface at some point D. Now it is a known fact, that the degree of illumination called *twilight* is perceived when the sun is 18° below the horizon of the spectator, that is, when the angle E *b* S or ACD is 18 degrees; therefore *b* C is the secant of 9 degrees (it is less, viz. about 8½ degrees, on account of refraction). We know the earth's radius to be about 3970 miles: hence we conclude *b* B to be about 45 miles; nay, a very sensible illumination is perceptible much farther from the sun's place than this, perhaps twice as far, and the air is sufficiently dense for reflecting a sensible light at the height of nearly 200 miles.

Experiment fixes no limit to the air's expansibility.

We have now seen that air is prodigiously expansible. None of our experiments have distinctly shown us any limit. But it does not follow that it is expansible without end; nor is this at all likely. It is much more probable that there is a certain distance of the parts in which they no longer repel each other; and this would be the distance at which they would arrange themselves if they were not heavy. But at the very summit of the atmosphere they will be a very small matter nearer to each other, on account of their gravitation to the earth. Till we know precisely the law of this mutual repulsion, we cannot say what is the height of the atmosphere.

Further observations.

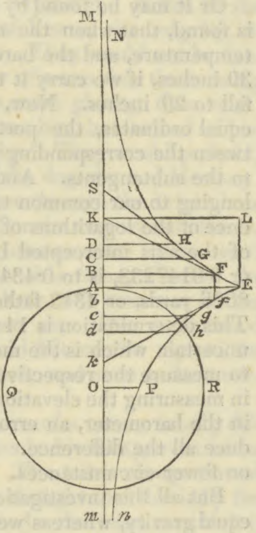
But if the air be an elastic fluid whose density is always proportionable to the compressing force, we can tell what is its density at any height above the surface of the earth: and we can compare the density so calculated with the density discovered by observation: for this last is measured by the height at which it supports mercury in the barometer. This is the direct measure of the pressure of the external air; and as we know the law of gravitation, we can tell what would be the pressure of air having the calculated density in all its parts.

Let us therefore suppose a prismatic or cylindric column of air reaching to the top of the atmosphere. Let this be divided into an indefinite number of strata of very small and equal depths or thickness; and let us, for greater simplicity, suppose at first that a particle of air is of the same weight at all distances from the centre of the earth.

The absolute weight of any one of these strata will on these conditions be proportional to the number of particles or the gravity of air contained in it; and since the depth of each stratum is the same, this quantity of air will evidently be as the density of the stratum. But the density of any stratum is as the compressing force; that is, as the pressure of the strata above it; that is, as their weight; that is, as their quantity of matter: therefore the quantity of air in each stratum is proportional to the quantity of air above it. The quantity in each stratum, however, is the difference between the column incumbent on its bottom and on its top; therefore these differences are proportional to the quantities of which they are the differences. But when there is a series of quantities which are proportional to their own differences, both the quantities and the differences are in continual or geometrical progression: for let a, b, c, be three such quantities that $b : c = a - b : b - c$, then by alternation and composition $a : b = b : c$, therefore the densities of these strata decrease in a geometrical progression; that is, when the elevations above the centre or surface of the earth increase, or their depths under the top of the atmosphere decrease, in an arithmetical progression, the densities decrease in a geometrical progression.

Height of the atmosphere.

Fig. 72.



Let ARQ (fig. 72), represent the section of the earth by a plane through its centre O, and let *m*OAM be a vertical line, and AE perpendicular to OA will be a horizontal line through A, a point on the earth's surface. Let AE be taken to represent the density of the air at A; and let DH, parallel to AE, be taken to AE as the density at D is to the density at A: it is evident, that if a logistic or logarithmic curve EHN be drawn, having AN for its axis, and passing through the points E and H, the density of the air at any other point C, in this vertical line, will be represented by CG, the ordinate to the curve in that point: for it is the property of this curve, that if portions AB, AC, AD, of its axis to be taken in arithmetical progression, the ordinates AE, BF, CG, DH, will be in the geometrical progression.

It is another fundamental property of this curve, that if EK or HS touch the curve in E or H, the subtangent AK or DS is a constant quantity.

And a third fundamental property is, that the infinitely extended area MAEN is equal to the rectangle KAEL of the ordinate and subtangent; and, in like manner, the area MDHN is equal to $SD \times DH$, or to $KA \times DH$; consequently the area lying beyond any ordinate is proportional to that ordinate.

These geometrical properties of this curve are all analogous to the chief circumstances in the constitution of the atmosphere, on the supposition of equal gravity. The area MCGN represents the whole quantity of aereal matter which is above C. For CG is the density at C, and CD is the thickness of the stratum between C and D; and therefore CGHD will be as the quantity of matter or air in it; and in like manner of all the others, and of their sums, or the whole area MCGN; and as each ordinate is proportional to the area above it, so each density, and the quantity of air in each stratum, is proportional to the quantity of air above it; and as the whole area MAEN is equal to the rectangle KAEL, so the whole air of variable density above A might be contained in a column KA, if, instead of being compressed by its own weight, it were without weight, and compressed by an external force equal to the pressure of the air at the surface of the earth. In this case, it would be of the uniform density AE, which it has at the surface of the earth, making what we have repeatedly called the homogeneous atmosphere.

Hence we derive this important circumstance, that the height of the homogeneous atmosphere is the subtangent of that curve, the ordinates of which are as the densities of the air at different heights, on the supposition of equal gravity. This curve may with propriety be called the *atmospherical*

Height of the atmosphere.

logarithmic; and as the different logarithmics are all characterised by their subtangents, it is of importance to determine this one.

It may be done by comparing the densities of mercury and air. For a column of air of uniform density, reaching to the top of the homogeneous atmosphere, is in equilibrio with the mercury in the barometer. Now, it is found, by the best experiments, that when mercury and air are of the temperature of 32° of Fahrenheit's thermometer, and the barometer stands at 30 inches, the mercury is nearly 10440 times denser than air. Therefore the height of the homogeneous atmosphere is 10440 times 30 inches, or 26100 feet, or 8700 yards, or 4350 fathoms, or 5 miles wanting 100 yards.

Or it may be found by observations on the barometer. It is found, that when the mercury and air are of the above temperature, and the barometer on the sea-shore stands at 30 inches, if we carry it to a place 884 feet higher it will fall to 29 inches. Now, in all logarithmic curves having equal ordinates, the portions of the axes intercepted between the corresponding pairs of ordinates are proportional to the subtangents. And the subtangents of the curve belonging to our common tables is 0·4342945, and the difference of the logarithms of 30 and 29, (which is the portion of the axis intercepted between the ordinates 30 and 29), or 0·0147233, is to 0·4342945 as 883 is to 26068 feet, or 8686 yards, or 4343 fathoms, or 5 miles wanting 114 yards. This determination is 14 yards less than the other, and it is uncertain which is the more exact. It is extremely difficult to measure the respective densities of mercury and air; and in measuring the elevation which produces a fall of one inch in the barometer, an error of 1-20th of an inch would produce all the difference. We prefer the last, as depending on fewer circumstances.

But all this investigation proceeds on the supposition of equal gravity, whereas we know that the weight of a particle of air decreases as the square of its distance from the centre of the earth increases. In order, therefore, that a superior stratum may produce an equal pressure at the surface of the earth, it must be denser, because a particle of it gravitates less. The density, therefore, at equal elevations, must be greater than on the supposition of equal gravity, and the law of diminution of density must be different.

$$\text{Make } OD : OA = OA : Od;$$
$$OC : OA = OA : Oc;$$
$$OB : OA = OA ; Ob; \text{ \&c.};$$

so that Od, Oc, Ob, OA, may be reciprocals to OD, OC, OB, OA; and through the points, A, b, c, d, draw the perpendiculars AE, bf, cg, dh, making them proportional to the densities in A, B, C, D: and let us suppose CD to be exceedingly small, so that the density may be supposed uniform through the whole stratum. Thus we have

$$OD \times Od = OA^2, = OC \times Oc$$
$$\text{and } Oc : Od : OD : OC;$$
$$\text{and } Oc : Oc - Od = OD : OD - OC,$$
$$\text{or } Oc : cd = OD : BC;$$
$$\text{and } cd : CD = Oc : OD;$$

or, because OC and OD are ultimately in the ratio o equality, we have

$$cd : CD = Oc : OC = OA^2 : OC^2,$$

and $cd = CD \times \frac{OA^2}{OC^2}$, and $cd \times cg = CD \times cg \times \frac{OA^2}{OC^2}$; but $CD \times cg \times \frac{OA^2}{OC^2}$ is as the pressure at C arising from the absolute weight of the stratum CD. For this weight is as the bulk, as the density, and as the gravitation of each particle jointly. Now CD expresses the bulk, cg the density, and $\frac{OA^2}{OC^2}$, the gravitation of each particle. Therefore, $cd \times cg$ is as the pressure on C arising from the weight of the stratum DC; but $cd \times cg$ is evidently the element of the curvilineal area A$mn$E, formed by the curve E$fghn$ and the ordinates AE, bf, cg, ah, &c. mn. Therefore the sum of all the elements, such as $c\,d\,h\,g$, that is, the area $c\,m\,n\,g$ below cg, will be as the *whole* pressure on C, arising from the gravitation of all the air above it; but, by the nature of air, this whole pressure is as the density which it produces, that is, as cg. Therefore the curve E$g\,n$ is of such a nature that the area lying below or beyond any ordinate cg is proportional to that ordinate. This is the property of the logarithmic curve, and E $g\,n$ is a logarithmic curve.

But farther, this curve is the same with EGN. For let B continually approach to A, and ultimately coincide with it. It is evident that the ultimate ratio of BA to Ab, and of BF to bf, is that of equality; and if EFK, Efk, be drawn, they will contain equal angles with the ordinate AE, and will cut off equal subtangents AK, Ak. The curves EGN, Egn are therefore the same, but in opposite positions.

Lastly, if OA, Ob, Oc, Od, &c. be taken in arithmetical progression decreasing, their reciprocals OA, OB, OC, OD, &c. will be in harmonical progression increasing, as is well known; but, from the nature of the logarithmic curve, when OA, Ob, Oc, Od, &c. are in arithmetical progression, the ordinates AE, bf, cg, dh, &c. are in geometrical progression. Therefore when OA, OB, OC, OD, &c. are in harmonical progression, the densities of the air at A, B, C, D, &c. are in geometrical progression; and thus may the density of the air at all elevations be discovered. Thus, to find the density of the air at K the top of the homogeneous atmosphere, make OK : OA=OA : OL, and draw the ordinate LT, LT is the density at K.

The celebrated Dr. Halley was the first who observed the relation between the density of the air and the ordinates of the logarithmic curve, or common logarithms. This he did on the supposition of equal gravity; and his discovery is acknowledged by Sir Isaac Newton in his *Principia*, ii. *prop.* 22, *schol.* Halley's dissertation on the subject is in No. 185 of the *Philosophical Transactions.* Newton, with his usual sagacity, extended the same relation to the true state of the case, where gravity is as the square of the distance inversely; and showed that when the distances from the earth's centre are in harmonic progression, the densities are in geometric progression. He shows, indeed, in general, what progression of the distance, on any supposition of gravity, will produce a geometrical progression of the densities, so as to obtain a set of lines OA, Ob, Oc, Od, &c. which will be logarithms of the densities.[1]

Finite density of the air at an infinite distance.

An important corollary is deducible from these principles, viz. that the air has a finite density at an infinite distance from the centre of the earth, namely, such as will be represented by the ordinate OP drawn through the centre. It may be objected to this conclusion, that it would infer an infinity of matter in the universe, and that it is inconsistent with the phenomena of the planetary motions, which appear to be performed in a space void of all resistance, and therefore of all matter. But this fluid must be so rare at great

---

[1] The subject was afterwards treated in a more familiar manner by Cotes in his *Hydrostatic Lectures*, and in his *Harmonia Mensurarum* by Dr. Brook Taylor, in his *Methodus Increment.*; by Wolf in his *Aerometria*; by Herman in his *Phoronomia*; and by Horsley in the *Philosophical Transactions*, tom. lxiv.

Atmosphere of the other planets.

distances, that the resistance will be insensible, even though the retardation occasioned by it has been accumulated for ages. Even at the very moderate distance of 500 miles, the rarity is so great that a cubic inch of common air expanded to that degree would occupy a sphere equal to the orbit of Saturn; and the whole retardation which this planet would sustain after some millions of years would not exceed what would be occasioned by its meeting one bit of matter of half a grain weight.

This being the case, it is not unreasonable to suppose the visible universe occupied by air, which, by its gravitation, will accumulate itself round every body in it, in a proportion depending on their quantities of matter, the larger bodies attracting more of it than the smaller ones, and thus forming an atmosphere about each. And many appearances warrant this supposition. Jupiter, Mars, Saturn, and Venus, are evidently surrounded by atmospheres. The constitution of these atmospheres may differ exceedingly from other causes. If the planet has nothing on its surface which can be dissolved by the air or volatilized by heat, the atmosphere will be continually clear and transparent, like that of the moon.

The atmosphere of Mars.

Mars has an atmosphere which appears precisely like our own, carrying clouds, or depositing snows; for when, by the obliquity of his axis to the plane of his eliptic, he turns his north pole towards the sun, it is observed to be occupied by a broad white spot. As the summer of that region advances, this spot gradually wastes, and sometimes vanishes, and then the south pole comes in sight, surrounded in like manner with a white spot, which undergoes similar changes. This is precisely the appearance which the snowy circumpolar regions of this earth will exhibit to an astronomer on Mars. It may not, however, be snow that we see; thick clouds will have the same appearances.

Of Jupiter.

The atmosphere of the planet Jupiter is also very similar to our own. It is diversified by streaks or belts parallel to his equator, which frequently change their appearance and dimensions, in the same manner as those tracks of similar sky which belong to different regions of this globe. There is a certain kind of weather that more properly belongs to a particular climate than to any other. This is nothing but a certain general state of the atmosphere which is prevalent there, though with considerable variations. This must appear to a spectator in the moon like a streak spread over that climate, distinguishing it from others. But the most remarkable similarity is in the motion of the clouds on Jupiter. They have plainly a motion from east to west relative to the body of the planet; for there is a remarkable spot on the surface of the planet, which is observed to turn round the axis in 9h. 51′ 16″; and there frequently appear variable and perishing spots in the belts, which sometimes last for several revolutions. These are observed to circulate in 9h. 55′ 0·5″. These numbers are the results of a long series of observations by Dr. Herschel. This plainly indicates a general current of the clouds westward, precisely similar to what a spectator in the moon must observe in our atmosphere arising from the trade winds. Mr. Schroeter has made the atmosphere of Jupiter a study for many years; and deduces from his observations that the motion of the variable spots is subject to great variations, but is always from east to west. This indicates variable winds.

Of Venus.

The atmosphere of Venus appears also to be like ours, loaded with vapours, and in a state of continual change of absorption and precipitation. About the middle of the seventeenth century the surface of Venus was pretty distinctly seen for many years chequered with irregular spots, which are described by Campani, Bianchini, and other astronomers in the south of Europe, and also by Cassini at Paris, and Hooke and Townley in England. But the spots became gradually more faint and indistinct; and, for near a century, have disappeared. The whole surface appears now of one uniform brilliant white. The atmosphere is probably filled with a reflecting vapour, thinly diffused through it, like water faintly tinged with milk. A great depth of this must appear as white as a small depth of milk itself; and it appears to be of a very great depth, and to be refractive like our air. For Sir William Herschel observed, by the help of his fine telescopes, that the illuminated part of Venus is considerably more than a hemisphere, and that the light dies gradually away to the bounding margin. This is the very appearance that the earth would make if furnished with such an atmosphere. The boundary of illumination would have a penumbra reaching about nine degrees beyond it. If this be the constitution of the atmosphere of Venus, she may be inhabited by beings like ourselves. They would not be dazzled by the intolerable splendour of a sun four times as big and as bright, and sixteen times more glaring than ours; for they would seldom or never see him, but instead of him an uniformly bright and white sky. They would probably never see a star or planet, unless the dog-star and Mercury; and perhaps the earth might pierce through the bright haze which surrounds their planet. For the same reason the inhabitants would not perhaps be incommoded by the sun's heat. It is indeed a very questionable thing, whether the sun would cause any heat, even here, if it were not for the chemical action of his rays on our air. This is rendered not improbable by the intense cold felt on the tops of the highest mountains, in the clearest air, and even under a vertical sun in the torrid zone.

Atmosphere of the other planets.

And of comets.

The atmosphere of comets seems of a nature totally different. This seems to be of inconceivable rarity, even when it reflects a very sensible light. The tail is always turned nearly away from the sun. It is thought that this is by the impulse of the solar rays. If this be the case, we think it might be discovered by the aberration and the refraction of the light by which we see the tail; for this light must come to our eye with a much smaller velocity than the sun's light, if it be reflected by repulsive or elastic forces, which there is every reason in the world to believe; and therefore the velocity of the reflected light will be diminished by all the velocity communicated to the reflecting particles. This is almost inconceivably great. The comet of 1680 went half round the sun in ten hours, and had a tail at least a hundred millions of miles long, which turned round at the same time, keeping nearly in the direction opposite to the sun. The velocity necessary for this is prodigious, approaching to that of light. And perhaps the tail extends much farther than we see it, but is visible only as far as the velocity with which its particles recede from the sun is less than a certain quantity, namely, what would leave a sufficient velocity for the reflected light to enable it to affect our eyes. And it may be demonstrated, that although the real form of the visible tail is concave on the anterior side to which the comet is moving, it may appear convex on that side, in consequence of the very great aberration of the light by which the remote parts are seen. All this may be discovered by properly contrived observations: and the conjecture merits attention. But of this digression there is enough; and we return to our subject, the constitution of our air.

The barometer used in measuring heights.

We have shown how to determine *a priori* the density of the air at different elevations above the surface of the earth. But the densities may be discovered in all accessible elevations by experiments; namely, by observing the heights of the mercury in the barometer. This is a direct measure of the pressure of the incumbent atmosphere; and this is proportional to the density which it produces. See Barometer and Barometrical Instruments.[1]

---

[1] For a table of the heights of the most remarkable mountains, many of which have been determined by the Barometer, see Physical Geography.

We have thus given an elementary account of the distinguishing properties of air as a heavy and compressible fluid, and of the general phenomena which are immediate consequences of these properties. This we have done in a set of propositions analogous to those which form the doctrines of hydrostatics. It remains to consider it in another point of view, namely, as moveable and inert. The phenomena consequent on these properties are exhibited in the velocities which air acquires by pressure, in the resistance which bodies meet with to their motion through the air, and in the impression which air in motion gives to bodies exposed to its action.

Doctrine of air acted on by equal and parallel gravity.

We shall first consider the motions of which air is susceptible when the equilibrium of pressure, whether arising from its weight or its elasticity, is removed; and, in the next place, we shall consider its action on solid bodies exposed to its current, and the resistance which it makes to their motion through it. In this consideration we shall avoid the extreme of generality, which renders the discussion too abstract and difficult, and adapt our investigation to the circumstances in which compressible fluids, of which air is taken for the representative, are most commonly found. We shall consider air therefore as it is commonly found in accessible situations, as acted on by equal and parallel gravity; and we shall consider it in the same order in which water is treated in a system of hydraulics.

In that science the leading problem is to determine with what velocity the water will move through a given orifice when impelled by some known pressure; and it has been found, that the best form in which this most difficult and intricate proposition can be put, is to determine the velocity of water flowing through this orifice when impelled by its weight alone. Having determined this, we can reduce to this case every question which can be proposed, for in place of the pressure of any piston or other mover, we can always substitute a perpendicular column of water or air whose weight shall be equal to the given pressure.

The velocity with which air ushes into a void.

The first problem, therefore, is to determine with what velocity air will rush into a void when impelled by its weight alone. This is evidently analogous to the hydraulic problem of water flowing out of a vessel. And here we must be contented with referring our readers to the solutions which have been given of that problem, and the demonstration that it flows with the velocity which a heavy body would acquire by falling from a height equal to the depth of the hole under the surface of the water in the vessel. In whatever way we attempt to demonstrate that proposition, every step, nay, every word, of the demonstration applies equally to the air, or to any fluid whatever. Or, if our readers should wish to see the connexion or analogy of the cases, we only desire them to recollect an undoubted maxim in the science of motion, that "when the moving force and the matter to be moved vary in the same proportion, the velocity will be the same." If therefore there be similar vessels of air, water, oil, or any other fluid, all of the height of a homogeneous atmosphere, they will all run through equal and similar holes with the same velocity; for in whatever proportion the quantity of matter moving through the hole be varied by a variation of density, the pressure which forces it out, by acting in circumstances perfectly similar, varies in the same proportion by the same variation of density. We must therefore assume it as the leading proposition, that "air rushes from the atmosphere into a void with the velocity which a heavy body would acquire by falling from the top of a homogeneous atmosphere."

It is known that air is about 840 times lighter than water, and that the pressure of the atmosphere supports water at the height of 33 feet nearly. The height therefore of a homogeneous atmosphere is nearly 33×840, or 27,720 feet. Moreover, to know the velocity acquired by any fall, recollect that a heavy body by falling one foot acquires the velocity of 8 feet per second; and that the velocities acquired by falling through different heights are as the square roots of the heights. Therefore to find the velocity corresponding to any height, expressed in feet per second, multiply the square root of the height by 8. We have therefore in the present instance $V = \sqrt{27,220}$, $= 8 \times 166.493$, $= 1332$ feet per second. This therefore is the velocity with which common air will rush into a void; and this may be taken as a standard number in pneumatics, as 16 and 32 are standard numbers in the general science of mechanics, expressing the action of gravity at the surface of the earth.

It is easy to see that greater precision is not necessary in this matter. The height of a homogeneous atmosphere is a variable thing, depending on the temperature of the air. If this reason seems any objection against the use of the number 1332, we may retain $8\sqrt{H}$ in place of it, where H expresses the height of a homogeneous atmosphere of the given temperature. A variation of the barometer makes no change in the velocity, nor in the height of the homogeneous atmosphere, because it is accompanied by a proportional variation in the density of the air. When it is increased $\frac{1}{10}$, for instance, the density is also increased $\frac{1}{10}$; and thus the expelling force and the matter to be moved are changed in the same proportion, and the velocity remains the same. Observe, we do not here consider the velocity which the air acquires after its issuing into the void by its continual expansion. This may be ascertained by the 39th proposition of Newton's *Principia*, book first. Nay, which appears very paradoxical, if a cylinder of air, communicating in this manner with a void, be compressed by a piston loaded with a weight, which presses it down as the air flows out, and thus keeps it of the same density, the velocity of efflux will still be the same, however great the pressure may chance to be; for the first and immediate effect of the load on the piston is to reduce the air in the cylinder to such a density that its elasticity shall exactly balance the load; and because the elasticity of air is proportional to its density, the density of the air will be increased in the same proportion with the load, that is, with the expelling power, for we are neglecting at present the weight of the included air as too inconsiderable to have any sensible effect. Therefore, since the matter to be moved is increased in the same proportion with the pressure, the velocity will be the same as before.

The velocity with which air rushes into a space containing rarer air.

It is equally easy to determine the velocity with which the air of the atmosphere will rush into a space containing rarer air. Whatever may be the density of this air, its elasticity, which follows the proportion of its density, will balance a proportional part of the pressure of the atmosphere; and it is the excess of this last only which is the moving force. The matter to be moved is the same as before. Let D be the natural density of the air, and δ the density of the air contained in the vessel into which it is supposed to run, and let P be the pressure of the atmosphere, and therefore equal to the force which impels it into a void; and let π be the force with which this rarer air would run into a void. We have $D : \delta = P : \pi$, and $\pi = \frac{P\delta}{D}$. Now the moving force in the present instance is $P - x$, or $P - \frac{P\delta}{D}$. Lastly, let V be the velocity of air rushing into a void, and v the velocity with which it will rush into this rarefied air.

It is a theorem in the motion of fluids, that the pressures are as the squares of the velocities af efflux.

Therefore $P : P - \frac{P\delta}{D} = V^2 : v^2$. Hence we derive $v^2 = V^2$

Air in motion.

$\times\,\overline{1-\frac{\delta}{D}}$, and $v\times V=\sqrt{1-\frac{\delta}{D}}\Big|$. We do not here consider the resistance which the air of the atmosphere will meet with from the inertia of that in the vessel which it must displace in its motion.

Here we see that there will always be a current into the vessel while δ is less than D.

We also learn the gradual diminution of the velocity as the vessel fills; for δ continually increases, and therefore $1-\frac{\delta}{D}$ continually diminishes.

It remains to determine the time t expressed in seconds, in which the air of the atmosphere will flow into this vessel from its state of vacuity till the air in the vessel has acquired any proposed density δ.

For this purpose let H, expressed in feet, be the height through which a heavy body must fall in order to acquire the velocity V, expressed also in feet per second. This we shall express more briefly in future, by calling it the height producing the velocity V. Let C represent the capacity of the vessel, expressed in cubic feet, and O the area or section of the orifice, expressed in superficial or square feet; and let the natural density of the air be D.

Since the quantity of aerial matter contained in a vessel depends on the capacity of the vessel and the density of the air jointly, we may express the air which would fill this vessel by the symbol CD when the air is in its ordinary state, and by Cδ when it has the density δ. In order to obtain the rate at which it fills, we must take the fluxion of this quantity Cδ. This is $C\dot{\delta}$; for C is a constant quantity, and δ is a variable or flowing quantity.

But we also obtain the rate of influx by our knowledge of the velocity, and the area of the orifice, and the density. The velocity is V, or $8\sqrt{H}$, at the first instant; and when the air in the vessel has acquired the density δ, that is, at the end of the time t, the velocity is $8\sqrt{H}\sqrt{1-\frac{\delta}{D}}$, or $8\sqrt{H}\sqrt{\frac{D-\delta}{D}}$, or $8\sqrt{H}\frac{\sqrt{D-\delta}}{\sqrt{D}}$.

The rate of influx therefore (which may be conceived as measured by the little mass of air which will enter during the time $\dot{t}$ with this velocity) will be $\frac{8\sqrt{HOD}\sqrt{D-\delta}\,\dot{t}}{\sqrt{D}}$, or $8\sqrt{H}O\sqrt{D}\sqrt{D-\delta}\,\dot{t}$, multiplying the velocity by the orifice and the density.

Here then we have two values of the rate of influx. By stating them as equal we have a fluxionary equation, from which we may obtain the fluents, that is, the time t in seconds necessary for bringing the air in the vessel to the density δ, or the density δ which will be produced at the end of any time t. We have the equation $8\sqrt{H}O\sqrt{D}\sqrt{D-\delta}\,\dot{t}=C\dot{\delta}$. Hence we derive $\dot{t}=\frac{C}{8\sqrt{H}O\sqrt{D}}\times\frac{\dot{\delta}}{\sqrt{D-\delta}}$.

Of this the fluent is $t=\frac{C}{4\sqrt{H}O\sqrt{D}}\times\sqrt{D-\delta}+A$, in which A is a conditional constant quantity. The condition which determines it is, that t must be nothing when δ is nothing, that is, when $\sqrt{D-\delta}=\sqrt{D}$; for this is evidently the case at the beginning of the motion. Hence it follows, that the constant quantity is $\sqrt{D}$, and the complete fluent, suited to the case, is

$$\frac{C}{4\sqrt{H}O\sqrt{D}}\times\overline{\sqrt{D}-\sqrt{D-\delta}}.$$

The motion ceases when the air in the vessel has acquired the density of the external air; that is, when $\delta=D$, or when $t=\frac{C}{4\sqrt{H}O\sqrt{D}}\times\sqrt{D},=\frac{C}{4\sqrt{H}O}$. Therefore the time of completely filling the vessel is $\frac{C}{4\sqrt{H}O}$.

Air in motion.

Let us illustrate this by an example in numbers.

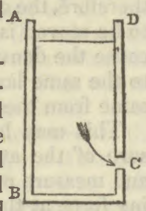
Supposing then that air is 840 times lighter than water, and the height of the homogeneous atmosphere 27,720 feet, we have $4\sqrt{H}=666$. Let us further suppose the vessel to contain 8 cubic feet, which is nearly a wine hogshead, and that the hole by which the air of the ordinary density, which we shall make $=1$, enters, is an inch square, or $\frac{1}{144}$ of a square foot. Then the time in seconds of completely filling it will be $\frac{8'}{\frac{1}{144}666}$, or $\frac{1152''}{666}$, or $1.7297''$. If the hole is only $\frac{1}{100}$ of a square inch, that is, if its side is $\frac{1}{10}$ of an inch, the time of completely filling the hogshead will be 173″ very nearly, or something less than three minutes.

If we make the experiment with a hole cut in a thin plate, we shall find the time greater nearly in the proportion of 63 to 100, for reasons obvious to all who have studied hydraulics. In like manner we can tell the time necessary for bringing the air in the vessel to $\frac{3}{4}$ths of its ordinary density. The only variable part of our fluent is the coefficient $-\sqrt{D-\delta}$, or $\sqrt{1-\delta}$. Let δ be $=\frac{3}{4}$, then $\sqrt{1-\delta}=\sqrt{\frac{1}{4}}=\frac{1}{2}$, and $\sqrt{1-\delta}=\frac{1}{2}$; and the time is $86\frac{1}{2}''$ very nearly when the hole is $\frac{1}{10}$ of an inch wide.

The velocity of air with the impulse of a weight moving down the vessel.

Let us now suppose that the air in the vessel ABCD (fig. 73.) is compressed by a weight acting on the cover AD, which is moveable down the vessel, and is thus expelled into the external air.

Fig. 73.



The immediate effect of this external pressure is to compress the air and give it another density. The density D of the external air corresponds to its pressure P. Let the additional pressure on the cover of the vessel be p, and the density of the air in the vessel be d. We shall have $P:P+p=D:d$; and therefore $p=P\times\frac{d-D}{D}$. Then, because the pressure which expels the air is the difference between the force which compresses the air in the vessel and the force which compresses the external air, the expelling force is p. And because the quantities of motion are as the forces which similarly produce them, we shall have $P:P\times\frac{d-D}{D}=MV:mv$; where M and m express the quantities of matter expelled, V expresses the velocity with which air rushes into a void, and v expresses the velocity sought. But because the quantities of aerial matter which issue from the same orifice in a moment are as the densities and velocities jointly, we shall have $MV:mv=DVV:dvv=DV^2:dv^2$. Therefore $P:p\frac{d-D}{D}=DV^2:dv$. Hence we deduce $V=V\sqrt{\frac{d-D}{d}}\Big|$.

We may have another expression of the velocity without considering the density. We had $P:P+p=D:d$; therefore $d=\frac{D\times\overline{P+p}}{P}$, and $d-D=\frac{D\times\overline{P+p}}{P}-D,=$

Air in motion.

$\frac{D\times P+p-DP}{P}$, and $\frac{d-D}{d}=\frac{D\times\overline{P+p}-DP}{D\times\overline{P+p}},=\frac{P+p-P}{P+p}$ $=\frac{p}{P+p}$; therefore $v=V\times\sqrt{\frac{p}{P+p}}$, which is a very simple and convenient expression.

Hitherto we have considered the motion of air as produced by its weight only. Let us now consider the effect of its elasticity.

The effect of the air's elasticity considered.

Let ABCD (fig. 73) be a vessel containing air of any density D. This air is in a state of compression; and if the compressing force be removed, it will expand, and its elasticity will diminish along with its density. Its elasticity in any state is measured by the force which keeps it in that state. The force which keeps common air in its ordinary density is the weight of the atmosphere, and is the same with the weight of a column of water 33 feet high. If therefore we suppose that this air, instead of being confined by the top of the vessel, is pressed down by a moveable piston carrying a column of water 33 feet high, its elasticity will balance this pressure as it balances the pressure of the atmosphere; and as it is a fluid, and propagates through every part the pressure exerted on any one part, it will press on any little portion of the vessel by its elasticity in the same manner as when loaded with this column.

The consequence of this reasoning is, that if the small portion of the vessel be removed, and thus a passage be made into a void, the air will begin to flow out with the same velocity with which it would flow when impelled by its weight alone, or with the velocity acquired by falling from the top of a homogeneous atmosphere, or 1332 feet in a second nearly.

But as soon as some air has come out, the density of the remaining air is diminished, and its elasticity is diminished; therefore, the expelling force is diminished. But the matter to be moved is diminished in the very same proportion, because the density and elasticity are found to vary according to the same law; therefore the velocity will continue the same from the beginning to the end of the efflux.

This may be seen in another way. Let P be the pressure of the atmosphere, which being the counter-balance and measure of the initial elasticity, is equal to the expelling force at the first instant. Let D be the initial density, and V the initial velocity. Let d be its density at the end of the time t of efflux, and v the contemporaneous velocity. It is plain that at the end of this time we shall have the expelling force $\pi=\frac{Pd}{D}$; for $D:d=P:\pi\left(=\frac{Pd}{D}\right)$.

These forces are proportional to the quantities of motion which they produce; and the quantities of motion are proportional to the quantities of matter M and m and the velocities V and v jointly: therefore we have $P:\frac{Pd}{D}=MV:mv$. But the quantities of matter which escape through a given orifice are as the densities and velocities jointly; that is, $M:m=DV:dv$: therefore $P:\frac{Pd}{D}=DV^2:dv^2$, and $P\times dv^2=\frac{PdDV^2}{D}=PdV^2$, and $V^2=v^2$, and $V=v$, and the velocity of efflux is constant. Hence follows, what appears very unlikely at first sight, that however much the air in the vessel is condensed, it will always issue into a void with the same velocity.

Quantity of air issuing into a void, and density.

In order to find the quantity of aerial matter which will issue during any time t, and consequently the density of the remaining air at the end of this time, we must get the rate of efflux. In the element of time $\dot{t}$ there issues (by what has been said above) the bulk $8\sqrt{HO}t$ (for the velocity V is constant); and therefore the quantity $8\sqrt{HO}d\dot{t}$. On the other hand, the quantity of air at the beginning was CD, C being the capacity of the vessel; and when the air has acquired the density d, the quantity is Cd; therefore the quantity which has run out in the time $\dot{t}$ must be the fluxion of $CD-Cd$, or $-C\dot{d}$. Therefore we have the equation $8\sqrt{HO}d\dot{t}=-C\dot{d}$, and $\dot{t}=\frac{-C\dot{d}}{8\sqrt{HO}d},=\frac{C}{8\sqrt{HO}}\times-\frac{\dot{d}}{d}$.

The fluent of this is $t=\frac{C}{8\sqrt{HO}}\log.d$. This fluent must be so taken that t may be $=o$ when $d=D$. Therefore the correct fluent will be $t=\frac{C}{8\sqrt{HO}}\log.\frac{D}{d}$, for $\log.\frac{D}{D}=\log.1,=o$. We deduce from this, that it requires an infinite time for the whole air of a vessel to flow out of it into a void. N.B. By log. d, &c. is meant the hyperbolic logarithm of d, &c.

When the vessel emits it into rarer air.

Let us next suppose that the vessel, instead of letting out its air into a void, emits it into air of a less density, which remains constant during the efflux, as we may suppose to be the case when a vessel containing condensed air emits it into the surrounding atmosphere. Let the initial density of the air in the vessel be δ, and that of the atmosphere D. Then it is plain that the expelling force is $P-\frac{PD}{\delta}$, and that after the time t it is $\frac{Pd}{\delta}-\frac{PD}{\delta}$. We have therefore $P-\frac{PD}{\delta}:\frac{Pd}{\delta}-\frac{PD}{\delta}=MV:mv,=\delta V^2:dv^2$. Whence we derive $v=V\sqrt{\frac{\delta\,\overline{d-D}}{d\,\overline{\delta-D}}}$.

From this equation we learn that the motion will be at an end when $d=D$: and if $\delta=D$ there can be no efflux.

Relation between the time and density.

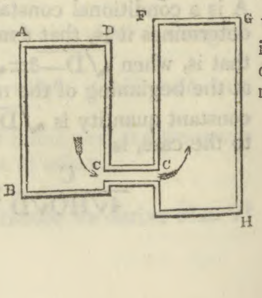
To find the relation between the time and the density, let H, as before, be the height producing the velocity V. The height producing the velocity of efflux v must be $H\times\frac{\delta\overline{d-D}}{d\overline{\delta-D}}$, and the little parcel of air which will flow out in the time t will $=8\sqrt{HO}d\dot{t}\sqrt{\frac{\delta\overline{d-D}}{d\overline{\delta-D}}}$. On the other hand, it is $=-C\dot{d}$.

Hence we deduce the fluxionary equation $\dot{t}=\frac{C\sqrt{\delta-D}}{8\sqrt{HO\sqrt{\delta}}}\times\frac{-\dot{d}}{\sqrt{d^2-Dd}}$. The fluent of this corrected so as to make $t=O$ when $d=\delta$, is $t=\frac{C\sqrt{\delta-D}}{8\sqrt{HO}\sqrt{\delta}}\times\log.\left(\frac{\delta-\frac{1}{2}D+\sqrt{\delta^2-Dd}}{d-\frac{1}{2}D+\sqrt{d^2-Dd}}\right)$.

And the time of completing the efflux, when $d=D$, is $\dot{t}=\frac{C\sqrt{\delta-D}}{8\sqrt{HO}\sqrt{\delta}}\times\log.\left(\frac{\delta-\frac{1}{2}D+\sqrt{\delta^2-D\delta}}{\frac{1}{2}D}\right)$.

When issuing from denser into rarer air.

Fig. 74.



Lastly, let ABCD, CFGH (fig. 74) be two vessels containing airs of different densities, and communicating by the orifice C, there will be a current from the vessel containing the denser air into that containing the rarer; suppose from ABCD into CFGH.

Let P be the elastic force of

Air in motion.

the air in ABCD, Q its density, and V its velocity, and D the density of the air in CFGH. And, after the time t, let the density of the air in ABCD be q, its velocity v, and the density of the air in CFGH be δ. The expelling force from ABCD will be $P-\frac{PD}{Q}$ at the first instant, and at the end of the time t it will be $\frac{Pq}{Q}-\frac{P\delta}{Q}$. Therefore we shall have $P-\frac{PD}{Q}:\frac{Pq}{Q}-\frac{P\delta}{Q}=QV^2:qv^2$, which gives $v=V\times\sqrt{\frac{Q(q-\delta)}{q(Q-D)}}$, and the motion will cease when $\delta=q$.

Let A be the capacity of the first vessel, and B that of the second. We have the second equation $AQ+BD=Aq+B\delta$, and therefore $\delta=\frac{A(Q-q)+BD}{qB(Q-D)}$. Substituting this value of δ in the former value of v, we have $v=\times\sqrt{\frac{Q[B(q-D)-A(Q-q)]}{qB(Q-D)}}$, which gives the relation between the velocity v and the density q.

In order to ascertain the time when the air in ABCD has acquired the density q, it will be convenient to abridge the work by some substitutions. Therefore make $Q(B+A)=M$, $BQD+BQ^2=N$, $BQ-BD=R$ and $\frac{N}{M}=m$. Then, proceeding as before, we obtain the fluxionary equation $8\sqrt{HO}q\frac{\sqrt{Mq-N}}{\sqrt{R}\sqrt{q}}\dot{t}=\dot{\overline{AQ-q}}=-A\dot{q}$, whence $\dot{t}=\frac{A\sqrt{R}}{8\sqrt{HO}\sqrt{M}}\times\frac{q}{\sqrt{q^2-mq}}$ of which the fluent, completed so that $t=o$ when $q=Q$, is $t=\frac{A\sqrt{R}}{8\sqrt{HO}\sqrt{M}}\times\log.\left(\frac{Q-\frac{1}{2}m+\sqrt{(Q^2mQ)}}{q-\frac{1}{2}m+\sqrt{(q^2mq)}}\right)$.

When air s expelled y force.

Some of these questions are of difficult solution, and they are not of frequent use in the more important and usual applications of the doctrines of pneumatics, at least in their present form. The cases of greatest use are when the air is expelled from a vessel by an external force, as when bellows are worked, whether of the ordinary form or consisting of a cylinder fitted with a movement piston. This last case merits a particular consideration; and, fortunately, the investigation is extremely easy.

Let AD (fig. 73) be considered as a piston moving downward with the uniform velocity f, and let the area of the piston be n times the area of the hole of efflux, then the velocity of efflux arising from the motion of the piston be nf. Add this to the velocity V produced by the elasticity of the air in the first question, and the whole velocity will be $V+nf$. It will be the same in the other. The problem is also freed from the consideration of the time of efflux. For this depends now on the velocity of the piston. It is still, however, a very intricate problem to ascertain the relation between the time and the density, even though the piston is moving uniformly; for at the beginning of the motion the air is of common density. As the piston descends, it both expels and compresses the air, and the density of the air in the vessel varies in a very intricate manner, as also its resistance or reaction on the piston. For this reason, a piston which moves uniformly by means of an external force, will never make an uniform blast by successive strokes; it will always be weaker at the beginning of the stroke. The best way for securing an uniform blast is to employ the external force only for lifting up the piston, and then to let the piston descend by its own weight. In this way it will quickly sink down, compressing the air, till its density and corresponding elasticity exactly balance the weight of the piston. After this the piston will descend equably, and the blast will be uniform. These observations and theorems will serve to determine the initial velocity of the air in all important cases of its expulsion. The philosopher will learn the rate of its efflux out of one vessel into another; the chemist will be able to calculate the quantities of the different gases which are employed in the curious experiments of the ingenious but unfortunate Lavoisier on combustion, and will find them extremely different from what he supposed; the engineer will learn how to proportion the motive force of his machine to the quantity of ærial matter which his bellows must supply. But it is not enough, for this purpose, that the air *begin* to issue in the proper quantity; we must see whether it be not affected by the circumstances of its subsequent passage.

Passage of air through pipes, &c.

All the modifications of motion which are observed in water conduits take place also in the passage of air through pipes and holes of all kinds. There is the same diminution of quantity passing through a hole in a thin plate that is observed in water. We know that, abating the small effect of friction, water issues with the velocity acquired by falling from the surface; and yet if we calculate by this velocity and by the area of the orifice, we shall find the quantity of water deficient nearly in the proportion of 63 to 100. This is owing to the water pressing towards the orifice from all sides, which occasions a contraction of the jet. The same thing happens in the efflux of air. Also the motion of water is greatly impeded by all contractions of its passage. These oblige it to accelerate its velocity, and therefore require an increase of pressure to force it through them, and this in proportion to the squares of the velocities. Thus, if a machine working a pump causes it to give a certain number of strokes in a minute, it will deliver a determined quantity of water in that time. Should it happen that the passage of the water is contracted to one half in any part of the machine, a thing which frequently happens at the valves, the water must move through this contraction with twice the velocity that it has in the rest of the passage. This will require four times the force to be exerted on the piston. Nay, if no part of the passage is narrower than the barrel of the pump, but on the contrary a part much wider, and if the conduit be again contracted to the width of the barrel, an additional force must be applied to the piston to drive the water through this passage, which would not have been necessary if the passage had not been widened in any part. It will require a force equal to the weight of a column of water of the height necessary for communicating a velocity, the square of which is equal to the difference of the squares of the velocities of the water in the wide and the narrow part of the conduit.

The same thing takes place in the motion of air, and therefore all contractions and dilatations must be carefully avoided, when we want to preserve the velocity unimpaired.

Air suffers retardation along pipes.

Air also suffers the same retardation in its motion along pipes. By not knowing, or not attending to that, engineers of the first reputation have been prodigiously disappointed in their expectations of the quantity of air which will be delivered by long pipes. Its extreme mobility and lightness hindered them from suspecting that it would suffer any sensible retardation. Dr. Papin, a most ingenious man, proposed this as the most effectual method of transferring the action of a moving power to a great distance. Suppose, for instance, that it was required to raise water out of a mine by a water-machine, and that there was no fall of water nearer than a mile's distance. He employed this water to drive a piston, which should compress the air in a cylinder communicating, by a long pipe, with another cylinder at the mouth of the mine. This second cylinder had a piston in it, whose rod was to give motion to the pumps at the mine. He expected, that as soon as the piston at the water-machine had compressed the air sufficiently, it would cause the air in the cylinder at the mine to force up its piston, and thus work the pumps. Dr. Hooke made many objections to the method, when laid before the Royal Society, and it was much debated there. But dynamics was at this time an infant science, and very little understood. Newton had not then taken any part in the business of the society, otherwise the true objections would not have escaped his sagacious mind. Notwithstanding Papin's great reputation as an engineer and mechanic, he could not bring his scheme into use in England; but afterwards, in France and in Germany, where he settled, he got some persons of great fortunes to employ him in this project; and he erected great machines in Auvergne and Westphalia for draining mines. But, so far from being effective machines, they would not even begin to move. He attributed the failure to the quantity of air in the pipe of communication, which must be condensed before it can condense the air in the remote cylinder. This indeed is true, and he should have thought of this earlier. He therefore diminished the size of this pipe, and made his water-machine exhaust instead of condensing, and had no doubt but that the immense velocity with which air rushes into a void would make a rapid and effectual communication of power. But he was equally disappointed here, and the machine at the mine stood still as before.

Nearly a century after this, a very intelligent engineer attempted a much more feasible thing of this kind at an ironfoundery in Wales. He erected a machine at a powerful fall of water, which worked a set of cylinder bellows, the blowpipe of which was conducted to the distance of a mile and a half, where it was applied to a blast furnace. But notwithstanding every care to make the conducting pipe very air-tight, of great size, and as smooth as possible, it would hardly blow out a candle. The failure was ascribed to the impossibility of making the pipe air-tight. But, what was surprising, above ten minutes elapsed after the action of the pistons in the bellows before the least wind could be perceived at the end of the pipe; whereas the engineer expected an interval of six seconds only.

No very distinct theory can be delivered on this subject; but we may derive considerable assistance in understanding the causes of the obstruction to the motion of water in long pipes, by considering what happens to air. The elasticity of the air, and its great compressibility, have given us the distinctest notions of fluidity in general, shewing us, in a way that can hardly be controverted, that the particles of a fluid are kept at a distance from each other, and from other bodies, by the corpuscular forces.

How fluids are obstructed in moving along canals.

The writers on hydrodynamics have always considered the obstruction to the motion of fluids along canals of any kind, as owing to something like the friction by which the motion of solid bodies on each other is obstructed; but we cannot form to ourselves any distinct notion of resemblance, or even analogy between them. The fact is, however, that a fluid running along a canal has its motion obstructed; and that this obstruction is greatest in the immediate vicinity of the solid canal, and gradually diminishes to the middle of the stream. It appears, therefore, that the parts of fluids can no more move among each other than among solid bodies, without suffering a diminution of their motion. The parts in physical contact with the sides and bottom are retarded by these immoveable bodies. The particles of the next stratum of fluid cannot preserve their initial velocities without overpassing the particles of the first stratum; and it appears from the fact that they are by this means retarded. They retard in the same manner the particles of the third stratum, and so on to the middle stratum or thread of fluid. It appears from the fact, therefore, that this sort of friction is not a consequence of rigidity alone, but that it is equally competent to fluids. Nay, since it is a matter of fact in air, and is even more remarkable there than in any other fluid, as we shall see by the experiments which have been made on the subject; and as our experiments on the compression of air shew us the particles of air ten times nearer to each other in some cases than in others (viz. when we see air a thousand times denser in these cases), and therefore force us to acknowledge that they are not in contact; it is plain that this obstruction has no analogy to friction, which supposes roughness or inequality of surface. No such inequality can be supposed in the surface of an aerial particle; nor would it be of any service in explaining the obstruction, since the particles do not rub on each other, but pass each other at some small and imperceptible distance. We must therefore have recourse to some other mode of explication. We shall apply this to air only in this place; and, since it is proved by the incontrovertible experiments of Canton, Zimmerman, and others, that water, mercury, oil, &c., are also compressible and perfectly elastic, the argument from this principle, which is conclusive in air, must equally explain the similar phenomenon in hydraulics.

Particles of air resist a change from a rectilineal to an undulating motion.

The most highly polished body which we know must be conceived as having an uneven surface when we compare it with the small spaces in which the corpuscular forces are exerted; and a quantity of air moving in a polished pipe may be compared to a quantity of small shot sliding down a channel with undulated sides and bottom. The row of particles immediately contiguous to the sides will therefore have an undulated motion: but this undulation of the contiguous particles of air will not be so great as that of the surface along which they glide; for not only every motion requires force to produce it, but also every change of motion. The particles of air resist this change from a rectilineal to an undulating motion; and, being elastic, that is, repelling each other and other bodies, they keep a little nearer to the surface as they are passing over an eminence, and their path is less incurvated than the surface. The difference between the motion of the particles of air and the particles of a fluid quite unelastic is, in this respect, somewhat like the difference between the motion of a spring-carriage and that of a common carriage. When the common carriage passes along a road not perfectly smooth, the line described by the centre of gravity of the carriage keeps perfectly parallel to that described by the axis of the wheels, rising and falling along with it. Now let a spring body be put on the same wheels and pass along the same road. When the axis rises over an eminence perhaps half an inch, sinks down again into the next hollow, and then rises a second time, and so on, the centre of gravity of the body describes a much straighter line; for upon the rising of the wheels, the body resists the motion, and compresses the springs, and thus remains lower than it would have been had the springs not been interposed. In like manner, it does not sink so low as the axle does when the wheels go into a hollow. And thus the motion of spring-carriages becomes less violently undulated than the road along which they pass. This illustration will, we hope, enable the reader to conceive how the deviation of the particles next to the sides and bottom of the canal from a rectilineal motion is less than that of the canal itself.

It is evident that the same reasoning will prove that the undulation of the next row of particles will be less than that of the first, that the undulation of the third row will be less than that of the second, and so on, as is represented in fig. 75. And thus it appears, that whilst the mass of air has a progressive motion along the pipe or canal, each particle is describing a waving line, of which a line parallel to the direction of the canal is the axis, cutting all these undulations. This axis of each undulated path will be straight or curved as the canal is, and the excursions of the path on each side of its axis will be less and less as the axis of the path is nearer to the axis of the canal.

Fig. 75.

Let us now see what *sensible* effect this will have; for all the motion which we here speak of is imperceptible. It is demonstrated in mechanics, that if a body moving with any velocity be deflected from its rectilineal path by a curved and perfectly smooth channel, to which the rectilineal path is a tangent, it will proceed along this channel with undiminished velocity. Now the path, in the present case, may be considered as perfectly smooth, since the particles do not touch it. It is one of the undulations which we are considering, and we may at present conceive this as without any subordinate inequalities. There should not, therefore, be any diminution of the velocity. Let us grant this of the absolute velocity of the particle; but what we observe is the velocity of the mass, and we judge of it perhaps by the motion of a feather carried along by it. Let us suppose a single atom to be a sensible object, and let us attend to two such particles, one at the side, and the other in the middle: although we cannot perceive the undulations of these particles during their progressive motions, we see the progressive motions themselves. Let us suppose, then, that the middle particle has moved without any undulation whatever, and that it has advanced ten feet. The lateral particle will also have moved ten feet; but this has not been in a straight line. It will not be so far advanced, therefore, in the direction of the canal; it will be left behind, and will appear to us to have been retarded in its motion; and in like manner each thread of particles will apparently be more and more retarded, as it recedes farther from the axis of the canal, or what is usually called the thread of the stream.

he undu-
tory mo-
on is a
al ob-
ruction.

And thus the observed fact is shewn to be a necessary consequence of what we know to be the nature of a compressible or elastic fluid; and that without supposing any diminution in the real velocity of each particle, there will be a diminution of the velocity of the sensible threads of the general stream, and a diminution of the whole quantity of air which passes along it during a given time.

Let us now suppose a parcel of air impelled along a pipe, which is *perfectly* smooth, out of a larger vessel, and issuing from this pipe with a certain velocity. It requires a certain force to change its velocity in the vessel to the greater velocity which it has in the pipe. This is abundantly demonstrated. How long soever we suppose this pipe, there will be no change in the velocity, or in the force to keep it up. But let us suppose that about the middle of this pipe there is a part of it which has suddenly got an undulated surface, however imperceptible. Let us further suppose that the final velocity of the middle thread is the same as before. In this case it is evident that the sum total of the motions of all the particles is greater than before, because the absolute motions of the lateral particles is greater than that of the central particle, which we suppose the same as before. This absolute increase of motion cannot be without an increase of propelling force: the force acting now, therefore, must be greater than the force acting formerly. Therefore, if only the former force had continued to act, the same motion of the central particle could not have been preserved, or the progressive motion of the whole stream must be diminished. And thus we see that this internal insensible undulatory motion becomes a real obstruction to the sensible motion which we observe, and occasions an expense of power.

otion.

Let us see what will be the consequence of extending this obstructing surface further along the canal. It must evidently be accompanied by an augmentation of the motion produced, if the central velocity be still kept up; for the particles which are now in contact with the sides do not continue to occupy that situation. The middle particles moving faster *forward* get over them, and in their turn come next the side; and as they are really moving equally fast, but not in the direction into which they are now to be forced, force is necessary for changing the direction also; and this is in addition to the force necessary for producing the undulations so minutely treated of. The consequence of this must be, that an additional force will be necessary for preserving a given progressive motion in a longer *obstructing* pipe, and that the motion produced in a pipe of greater length by a given force will be less than in a shorter one, and the efflux will be diminished.

There is another consideration which must have an influence here. Nothing is more irrefragably demonstrated than the necessity of an additional force for producing an efflux through any contraction, even though it should be succeeded by a dilatation of the passage. Now both the inequalities of the sides and the undulations of the motions of each particle are equivalent to a succession of contractions and dilatations; although each of these is next to infinitely small; their number is also next to infinitely great, and therefore the total effect may be sensible.

There are other obstructions, as angular asperities.

We have hitherto supposed that the absolute velocity of the particles was not diminished; this we did, having assumed that the interval of each undulation of the sides was without inequalities. But this was gratuitous; it was also gratuitous that the sides were only undulated. We have no reason for excluding angular asperities. These will produce, and most certainly often produce, real diminutions in the velocity of the contiguous particles; and this must extend to the very axis of the canal, and produce a diminution of the sum total of motion; and in order to preserve the same sensible progressive motion, a greater force must be employed. This is all that can be meant by saying that there is a resistance to the motion of air through long pipes.

There remains another cause of diminution, viz. the want of perfect fluidity, whether arising from the dissemination of solid particles in a real fluid, or from the viscidity of the fluid. We shall not insist on this at present, because it cannot be shown to obtain in air, at least in any case which deserves consideration. It seems of no importance to determine the motion of air hurrying along with it soot or dust. The effect of fogs on a particular modification of the motion of air will be considered under another head. What has been said on this subject is sufficient for our purpose, as explaining the prodigious and unexpected obstruction to the passage of air through long and narrow pipes. We are able to collect an important maxim from it, viz. that all pipes of communication should be made as wide as circumstances will permit; for it is plain that the obstruction depends on the internal surface, and the force to overcome it must be in proportion to the mass of matter which is in motion. The first increases as the diameter of the pipe, and the last as the square. The obstruction must therefore bear a greater proportion to the whole motion in a small pipe than in a large one.

The law of retardation unknown.

It were very desirable to know the law by which the retardation extends from the axis to the sides of the canal, and the proportion which subsists between the lengths of the canal and the forces necessary for overcoming the obstructions when the velocity is given; as also whether the proportion of the obstruction to the whole motion varies with the velocity; but all this is unknown. It does not, however, seem a desperate case in air; we know pretty distinctly the law of action among its particles, viz. that their mutual repulsions are inversely as their distances. This promises to enable us to trace the progress of undulation from the sides of the canal to the axis.

The rate of increase not as the square of the velocities.

We can see that the retardations will not increase so fast as the square of the velocity. Were the fluid incompressible, so that the undulatory path of a particle were invariable, the deflecting forces by which each individual particle is made to describe its undulating path would be precisely such as arise from the path itself and the motion in it; for each particle would be in the situation of a body moving along a fixed path. But in a very compressible fluid, such

Air in motion.

as air, each particle may be considered as a solitary body, actuated by a projectile and a transverse force, arising from the action of the adjoining particles. Its motion must depend on the adjustment of these forces, in the same manner as the elliptical motion of a planet depends on the adjustment of the force of projection, with a gravitation inversely proportional to the square of the distance from the focus. The transverse force in the present case has its origin in the pressure on the air which is propelling it along the pipe; this, by squeezing the particles together, brings their mutual repulsion into action. Now it is the property of a perfect fluid, that a pressure exerted on any part of it is propagated equally through the whole fluid; therefore the transverse forces which are excited by this pressure are proportional to the pressure itself; and we know that the pressures exerted on the surface of a fluid, so as to expel it through any orifice, or along any canal, are proportional to the squares of the velocities which they produce. Therefore, in every point of the undulatory motion of any particle, the transverse force by which it is deflected into a curve is proportional to the square of its velocity. When this is the case, a body would continue to describe the same curve as before; but, by the very compression, the curvatures are increased, supposing them to remain similar. This would require an increase of the transverse forces; but this is not to be found; therefore the particle will not describe a similar curve, but one which is less incurvated in all its parts; consequently the progressive velocity of the whole, which is the only thing perceivable by us, will not be so much diminished; that is, the obstructions will not increase so fast as they would otherwise do, or as the squares of the velocities.

This reasoning is equally applicable to all fluids, and is abundantly confirmed by experiments in hydraulics, as we shall see when considering the motion of rivers. We have taken this opportunity of delivering our notions on this subject; because, as we have often said, it is in the avowed discrete constitution of air that we see most distinctly the operation of those natural powers which constitute fluidity in general.

Bossut's experiments on pipes and canals.

We would beg leave to mention a form of experiment for discovering the law of retardation with considerable accuracy. Experiments have been made on pipes and canals. M. Bossut, in his *Hydrodynamique*, has given a very beautiful set made on pipes of an inch and two inches in diameter, and 200 feet in length; but although these experiments are very instructive, they do not give us any rule by which we can extend the result to pipes of greater length and different diameters.

Let a smooth cylinder be set upright in a very large vessel or pond, and be moveable round its axis; let it be turned round by means of a wheel and pulley with an uniform motion and determined velocity. It will exert the same force on the contiguous water which would be exerted on it by water turning round it with the same velocity; and as this water would have its motion gradually retarded by the fixed cylinder, so the moving cylinder will gradually communicate motion to the surrounding water. We should observe the water gradually dragged round by it; and the vortex would extend farther and farther from it as the motion is continued, and the velocities of the parts of the vortex will be less and less as we recede from the axis. Now, we apprehend, that when a point of the surface of the cylinder has moved 200 feet, the *motion* of the water at different distances from it will be similar and proportional to, if not precisely the same with, *retardations* of water flowing 200 feet at the same distance from the side of a canal; at any rate, the two are susceptible of an accurate comparison, and the law of retardation may be accurately deduced from observations made on the motions of this vortex.

Wind.

Air in motion is a very familiar object of observation; and it is interesting. In all languages it has got a name; we call it wind; and it is only upon reflection that we consider air as wind in a quiescent state. Many persons hardly know what is meant when air is mentioned; but they cannot refuse that the blast from a bellows is the expulsion of what they contained; and thus they learn that wind is air in motion.

Velocity o wind.

The velocity of wind not easily discovered.

It is of consequence to know the velocity of wind; but no good and unexceptionable method has been contrived for this purpose. The best seems to be by measuring the space passed over by the shadow of a cloud; but this is extremely fallacious. In the first place, it is certain, that although we suppose that the cloud has the velocity of the air in which it is carried along, this is not an exact measure of the current on the surface of the earth; we may be almost certain that it is greater; for air, like all other fluids, is retarded by the sides and bottom of the channel in which it moves. But, in the next place, it is very gratuitous to suppose, that the velocity of the cloud is the velocity of the stratum of air between the cloud and the earth; we are almost certain that it is not. It is abundantly proved by Dr. Hutton of Edinburgh, that clouds are always formed when two parcels of air of different temperatures mix together, each containing a proper quantity of vapour in the state of chemical solution. We know that different strata of air will frequently flow in different directions for a long time. In 1781, whilst a great fleet rendezvoused in Leith Roads during the Dutch war, there was a brisk easterly wind for about five weeks; and, during the last fortnight of this period, there was a brisk westerly current at the height of about three-fourths of a mile. This was distinctly indicated by frequent fleecy clouds at a great distance above a lower stratum of these clouds, which were driving all this time from the eastward. A gentleman who was present at the siege of Quebec in 1759, stated that one day whilst there blew a gale from the west, so hard that the ships at anchor in the river were obliged to strike their topmasts, and it was with the utmost difficulty that some well-manned boats could row against it, carrying some artillery stores to a post above the town, several shells were thrown from the town to destroy the boats; one of the shells burst in the air near the top of its flight, which was about half a mile high. The smoke of this bomb remained in the same spot for above a qaarter of an hour, like a great round ball, and gradually dissipated by diffusion, without removing many yards from its place. When, therefore, two strata of air come from different quarters, and one of them flows over the other, it will be only in the contiguous surfaces that a precipitation of vapour will be made. This will form a thin fleecy cloud; and it will have a velocity and direction which neither belongs to the upper nor to the lower stratum of air which produced it. Should one of these strata come from the east and the other from the west with equal velocities, the cloud formed between them will have no motion at all; should one come from the east, and the other from the north, the cloud will move from the north-east with a greater velocity than either of the strata. So uncertain then is the information given by the clouds either of the velocity or the direction of the wind. A thick smoke from a furnace will give us a much less equivocal measure; and this, combined with the effects of the wind in impelling bodies, or deflecting a loaded plane from the perpendicular, or other effects of this kind, may give us measures of the different currents of wind with a precision sufficient for all practical uses.

The result of Smeaton's observations.

The celebrated engineer, Mr. John Smeaton, has given, in the 51st volume of the *Philosophical Transactions*, the velocities of wind corresponding to the usual denominations in our language. These are founded on a great number of observations made by himself in the course of his practice in erecting wind-mills. They are contained in the following table:—

elocity of wind.

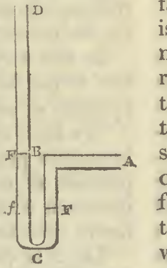
Miles per hour.	Feet per second.	Names.
1	1·47	
2	2·93	Light airs.
3	4·40	
4	5·87	Breeze.
5	7·33	
10	14·67	Brisk gale.
15	22·	
20	29·34	Fresh gale.
25	36·57	
30	44·01	Strong gale.
35	51·34	
40	58·68	Hard gale.
45	66·01	
50	73·35	Storm.
60	88·02	
80	117·36	Hurricane, tearing up trees, overturning buildings, &c.[1]
100	146·70	

ccount of r. Lind's nemome- r.

One of the most ingenious and convenient methods for measuring the velocity of the wind is to employ its pressure in supporting a column of water, in the same way as Mr. Pitot measures the velocity of a current of water. We believe that it was first proposed by Dr. James Lind of Windsor, a gentleman eminent for his great knowledge in all the branches of natural science, and for his ingenuity in every matter of experiment or practical application.

His anemometer consists of a glass tube of the form ABCD (fig. 76), open at both ends, and having the branch AB at right angles to the branch CD. This tube contains a few inches of water or any fluid (the lighter the better); it is held with the part CD upright, and AB horizontal and in the direction of the wind; that is, with the mouth A fronting the wind. The wind acts in the way of pressure on the air in AB, compresses it, and causes it to press on the surface of the liquor; forcing it down to F, whilst it rises to E in the other leg. The velocity of the wind is concluded from the difference E*f* between the heights of the liquor in the legs. As the wind does not generally blow with uniform velocity, the liquor is apt to dance in the tube, and render the observation difficult and uncertain; to remedy this, it is proper to contract very much the communication at C between the two legs. If the tube has half an inch of diameter, and it should not have less, a hole of 1-50th of an inch is large enough; indeed the hole can hardly be too small, nor the tubes too large.

Fig. 76.

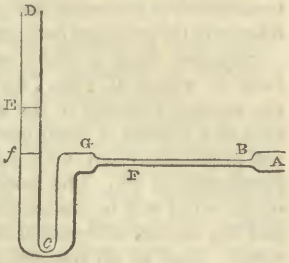


This instrument is extremely ingenious, and will undoubtedly give the proportions of the velocities of different currents with the greatest precision; for in whatever way the pressure of wind is produced by its motion, we are certain that the different pressures are as the squares of the velocities; if, therefore, we can obtain one certain measure of the velocity of the wind, and observe the degree to which the pressure produced by it raises the liquor, we can at all other times observe the pressures and compute the velocities from them, making proper allowances for the temperature and the height of the mercury in the barometer; because the velocity will be in the subduplicate ratio of the density of the air inversely when the pressure is the same.

It is usually concluded, that the velocity of the wind is that which would be acquired by falling from a height which is to E*f* as the weight of water is to that of an equal bulk of air. Thus, supposing air to be 840 times lighter than water, and that E*f* is 9-10ths of an inch, the velocity will be about 63 feet per second, which is that of a very hard gale, approaching to a storm. Hence we see by the bye, that the scale of this instrument is extremely short, and that it would be a great improvement of it to make the leg CD not perpendicular, but very much sloping; or perhaps the following form of the instrument will give it all the perfection of which it is capable. Let the horizontal branch AB (fig. 77) be contracted at B, and continued horizontally for several inches BG of a much smaller bore, and then turned down for two or three inches GC, and then upwards with a wide bore. To use the instrument, hold it with the part DC perpendicular; and (having sheltered the mouth A from the wind) pour in water at D till it advances along GB to the point B, which is made the beginning of the scale; the water in the upright branch standing at F in the same horizontal line with BG. Now, turn the mouth A to the wind; the air in AB will be compressed and will force the water along BG to F, and cause it to rise from *f* to E; and the range *f*E will be to the range BF on the scale as the section of the tube BG to that of CD. Thus, if the width of DC be half an inch, and that of BG 1-10th, we shall have 25 inches in the scale for one inch of real pressure E*f*.

Velocity of wind.

Fig. 77.



But it has not been demonstrated in a very satisfactory manner, that the velocity of the wind is that acquired by falling through the height of a column of air whose weight is equal to that of the column of water E*f*. Experiments made with Pitot's tube in currents of water show that several corrections are necessary for conducting the velocity of the current from the elevations in the tube: these corrections may however be made, and safely applied to the present case; and then the instrument will enable us to conclude the velocity of the wind immediately, without any fundamental comparison of the elevation, with a velocity actually determined upon other principles. The chief use which we have for this information is in our employment of wind as an impelling power, by which we can actuate machinery or navigate ships. These are very important applications of pneumatical doctrines, and merit a particular consideration; and this naturally brings us to the last part of our subject, viz. the consideration of the impulse of air on bodies exposed to its action, and the resistance which it opposes to the passage of bodies through it.

This subject important but difficult.

This is a subject of the greatest importance, being the foundation of that art which has done the greatest honour to the ingenuity of man, and the greatest service to human society, by connecting together the most distant inhabitants of this globe, and making a communication of benefits which would otherwise have been impossible; we mean the art of Navigation or Seamanship. Of all the machines which human art has constructed, a ship is not only the greatest and most magnificent, but also the most ingenious and intricate; and the clever seaman possesses a knowledge founded on the most difficult and abstruse doctrines of mechanics. The seaman probably cannot give any account of his own science; and he possesses it rather by a kind of intuition than by any process of reasoning; but the success and efficiency of all the mechanism of this complicated engine, and the propriety of all the manœuvres which the seaman practises, depend on the invariable laws of mechanics; and a thorough knowledge of these would enable an intelligent person not only to understand the machine and the manner of working it, but to improve both.

Unfortunately this is a subject of very great difficulty; and although it has employed the genius of Newton, who has con-

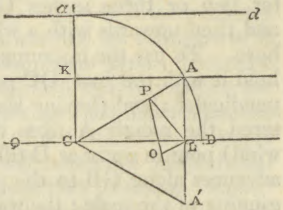
---

[1] See also some valuable experiments by him on this subject, *Philosophical Transactions*, 1760 and 1761.

Velocity of wind.

sidered it with great care, and his followers have added more to his labours on this subject than on any other, it still remains in a very imperfect state. A minute discussion of this subject cannot therefore be expected in a work like this; we must content ourselves with such a general statement of the most approved doctrine on the subject as shall enable our readers to conceive it distinctly, and judge with intelligence and confidence of the practical deductions which may be made from it.

Fig. 78.



Suppose then a plane surface, of which aC (fig. 78), is the section, exposed to the action of a stream of wind blowing in the direction QC, perpendicular to aC. The motion of the wind will be obstructed, and the surface aC pressed forward. And as all impulse or pressure is exerted in a direction perpendicular to the surface, and is resisted in the opposite direction, the surface will be impelled in the direction CD, the continuation of QC. And as the mutual actions of bodies depend on their relative motions, the force acting on the surface aC will be the same, if we shall suppose the air at rest, and the surface moving equally swift in the opposite direction. The resistance of the air to the motion of the body will be equal to the impulse of the air in the former case. Thus resistance and impulse are equal and contrary.

Air moving with a double velocity generally impels as the square of that velocity.

If the air be moving twice as fast, its particles will give a double impulse; but in this case a double number of particles will exert their impulse in the same time. The impulse will therefore be fourfold, and in general it will be as the square of the velocity; or if the air and body be both in motion, the impulse and resistance will be proportional to the square of the relative velocity. This is the first proposition on the subject, and it appears very consistent to reason. There will therefore be some analogy between the force of the air's impulse or the resistance of a body, and the weight of a column of air incumbent on the surface; for it is a principle in the action of fluids, that the heights of the columns of fluid are as the squares of the velocities which their pressures produce. Accordingly, the second proposition is, that the absolute impulse of a stream of air, blowing perpendicularly on any surface, is equal to the weight of a column of air which has that surface for its base, and for its height the space through which a body must fall in order to acquire the velocity of the air.

Thirdly, Suppose the surface AC equal to aC no longer to be perpendicular to the stream of air, but inclined to it in the angle ACD, which we shall call the *angle of incidence;* then, by the resolution of forces, it follows, that the action of each particle is diminished in the proportion of radius to the sine of the angle of incidence, or of AC to AL, AL being perpendicular to CD.

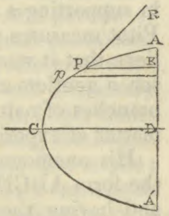
Again: Draw AK parallel to CD. It is plain that no air lying farther from CD than KA is will strike the plane. The quantity of impulse therefore is diminished still farther in the proportion of aC to KC, or of AC to AL. Therefore, on the whole, the absolute impulse is diminished in the proportion of AC^2 to AL^2: hence the proposition, that the impulse and resistance of a given surface are in the proportion of the square of the sine of the angle of incidence.

Fourthly, This impulse is in the direction PL, perpendicular to the impelled surface, and the surface tends to move in this direction: but suppose it moveable only in some other direction PO that we wish to employ this impulse, its action is therefore oblique; and if we wish to know the intensity of the impulse in this direction, it must be diminished still farther in the proportion of radius to the cosine of the angle LPO or sine of CPO. Hence the general proposition: *The effective impulse is as the surface, as the square of the velocity of the wind, as the square of the sine of the angle of incidence, and as the sine of the obliquity jointly,* which we may express by the symbol $R=S\cdot V^{2}\cdot sin.^{2}\cdot I\cdot sin.\ O$; and as the impulse depends on the density of the impelling fluid, we may take in every circumstance by the equation $R=S\cdot D\cdot V^{2}\cdot sin.^{2}\cdot I\cdot sin.\ O$. If the impulse be estimated in the direction of the stream, the angle of obliquity ACD is the same with the angle of incidence, and the impulse in this direction is as the surface, as the square of the velocity, and as the cube of the angle of incidence jointly.

It evidently follows from these premises, that if ACA′ be a wedge, of which the base AA′ is perpendicular to the wind, and the angle ACA′ bisected by its direction, the direct or perpendicular impulse on the base is to the oblique impulse on the sides as radius to the square of the sine of half the angle ACA′.

The same must be affirmed of a pyramid or cone ACA′, of which the axis is in the direction of the wind.

Fig. 79.



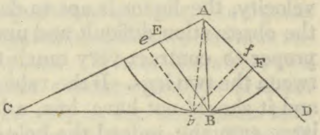
If ACA′ (fig. 79,) represent the section of a solid, produced by the revolution of a curve line APC round the axis CD, which lies in the direction of the wind, the impulse on this body may be compared with the direct impulse on this base, or the resistance to the motion of this body through the air may be compared with the direct resistance of its base, by resolving its surface into elementary planes Pp, which are coincident with a tangent plane PR, and comparing the impulse on P p with the direct impulse on the corresponding part K k of the base.

In this way it follows that the impulse on a sphere is one half of the impulse on its great circle, or on the base of a cylinder of equal diameter.

We shall conclude this sketch of the doctrine with a very important proposition to determine the most advantageous position of a plane surface, when required to move in one direction while it is impelled by the wind blowing in a different direction. Thus,

Inference from this doctrine.

Fig. 80.



Let AB (fig. 80) be the sail of a ship, CA the direction in which the wind blows, and AD the line of the ship's course. It is required to place the yard AC in such a position that the impulse of the wind upon the sail may have the greatest effect possible in impelling the ship along AD.

Let AB, Ab, be two positions of the sail very near the best position, but on opposite sides of it. Draw BE, $b\,e$, perpendicular to CA, and BF, $b\,f$, perpendicular to AD, calling AB radius; it is evident that BE, BF, are the sines of impulse and obliquity, and that the effective impulse is $BE^2\times BF$, or $b\,e^2\times b\,f$. This must be a maximum.

Let the points B, b, continually approach and ultimately coincide; the chord b B will ultimately coincide with a straight line CBD touching the circle in B; the triangles CBE, $c\,b\,e$ are similar, as also the triangles DBF, D $b\,f$: therefore $BE^2 : b\,e^2 = BC^2 : b\,c^2$, and $BF : b\,f = BD : b\,D$; and $BE^2\times BF : b\,e^2\times b\,f = CB^2\times BD : c\,b^2\times bD$. Therefore when AB is in the best position, so that $BE^2\times BF$ is greater than $b\,e^2\times b\,f$, we shall have $CB\times BD$ greater than $Cb^2\times bD$, or $cB^2\times BD$ is also a maximum. This we know to be the case when $CB=2BD$: therefore the sail must be so placed that the tangent of the angle of incidence shall be double of the tangent of the angle of the sail and keel.

In a common windmill the angle CAD is necessarily a right angle; for the sail moves in a circle to which the wind is perpendicular: therefore the best angle of the sail and axle will be 54° 44′ nearly.

Velocity of wind.

Such is the theory of the resistance and impulse of the air. It is extremely simple and of easy application. In all physical theories there are assumptions which depend on other principles, and those on the judgment of the naturalist; so that it is always proper to confront the theory with experiment. There are even circumstances in the present case which have not been attended to in the theory. When a stream of air is obstructed by a solid body, or when a solid body moves along in air, the air is condensed before it and rarefied behind. There is therefore a pressure on the anterior parts arising from this want of equilibrium in the elasticity of the air. This must be superadded to the force arising from the impetus or inertia of the air. We cannot tell with precision what may be the amount of this condensation; it depends on the velocity with which any condensation diffuses itself. Also, if the motion be so rapid that the pressure of the atmosphere cannot make the air immediately occupy the place quitted by the body, it will sustain this pressure on its fore part to be added to the other forces.

The prin- pal expe- ments on is subject

Experiments on this subjects are by no means numerous; at least such experiments as can be dependend on for the foundation of any practical application. The first that have this character are those published by Mr. Robins in 1742, in his *Treatise on Gunnery*. They were repeated with some additions by the Chevalier Borda, and some account of them published in the *Memoirs of the Academy of Sciences in* 1763. In the *Philosophical Transactions of the Royal Society of London*, vol. lxxiii., there are some experiments of the same kind on a larger scale by Mr. Edgeworth. These were all made in the way described in our account of Mr. Robins's improvements in gunnery. Bodies were made to move with determined velocities, and the resistances were measured by weights. In all these experiments the resistances were found very exactly in the proportion of the squares of the velocities; but they were found considerably greater than the weight of the column of air, whose height would produce the velocity in a falling body. Mr. Robins's experiments on a square of 16 inches, describing 25.2 feet per second, indicate the resistance to be to this weight nearly as 4 to 3. Borda's experiments on the same surface state the disproportion still greater.

The resistances are found not to be in the proportion of the surfaces, but increase considerably faster. Surfaces of 9, 16, 36, and 81 inches, moving with one velocity, had resistances in the proportion of 9, $17\frac{1}{2}$, $42\frac{3}{4}$, and $104\frac{3}{4}$.

Now as this deviation from the proportion of the surfaces increases with great regularity, it is most probable that it continues to increase in surfaces of still greater extent; and these are the most generally to be met with in practice in the action of wind on ships and mills.

Borda's experiments on 81 inches show that the impulse of wind moving one foot per second is about $\frac{1}{500}$ of a pound on a square foot. Therefore to find the impulse on a foot corresponding to any velocity, divide the square of the velocity by 500, and we obtain the impulse in pounds. Mr. Rouse of Leicestershire made many experiments, which are mentioned with great approbation by Mr. Smeaton. His great sagacity and experience in the erection of windmills, oblige us to pay a considerable deference to his judgment. These experiments confirm our opinion, that the impulses increase faster than the surfaces. The following table was calculated from Mr. Rouse's observations, and may be considered as pretty near the truth:

Velocity of wind.

Velocity in feet.	Impulse on a foot in pounds.	Velocity in feet.	Impulse on a foot in pounds.
0	0,000	30	2,059
10	0,229	40	3,660
20	0,915	50	5,718
60	8,234	110	27,675
70	11,207	120	32,926
80	14,638	130	38,654
90	18,526	140	44,830
100	22,872	150	51,462

If we multiply the square of the velocity in feet by 16, the product will be the impulse or resistance on a square foot in grains, according to Mr. Rouse's numbers.

The greatest deviation from the theory occurs in the oblique impulses. Mr. Robins compared the resistance of a wedge, whose angle was 90°, with the resistance of its base; and instead of finding it less in the proportion of $\sqrt{2}$ to 1, as determined by the theory, he found it greater in the proportion of 55 to 68 nearly; and when he formed the body into a pyramid, of which the sides had the same surface and the same inclination as the sides of the wedge, the resistance of the base and face were now as 55 to 39 nearly; so that here the same surface with the same inclination had its resistance reduced from 68 to 39 by being put into this form. Similar deviations occur in the experiments of the Chevalier Borda; and it may be collected from both, that the resistances diminish more nearly in the proportion of the sines of incidence than in the proportion of the squares of those sines.

The irregularity in the resistance of curved surfaces is as great as in plane surfaces. In general, the theory gives the oblique impulses on plane surfaces much too small, and the impulses on curved surfaces too great. The resistance of a sphere does not exceed the fourth part of the resistance of its great circle, instead of being its half; but the anomaly is such as to leave hardly any room for calculation. It would be very desirable to have the experiments on this subject repeated in a greater variety of cases, and on larger surfaces, so that the errors of the experiments may be of less consequence. Till this matter is reduced to some rule, the art of working ships must remain very imperfect, as must also the construction of windmills.

The resistance of air in the motion of projectiles.

The case in which we are most interested in the knowledge of the resistance of the air is the motion of bullets and shells. Writers on artillery have long been sensible of the great effect of the air's resistance. It seems to have been this consideration that chiefly engaged Sir Isaac Newton to consider the motion of bodies in a resisting medium. A proposistion or two would have sufficed for showing the incompatibility of the planetary motions with the supposition that the celestial spaces were filled with a fluid matter; but he has with great solicitude considered the motion of a body projected on the surface of the earth, and its deviation from the parabolic track assigned by Galileo. He has bestowed more pains on this problem than any other in his whole work; and his investigation has pointed out almost all the improvements which have been made in the application of mathematical knowledge to the study of nature. Nowhere does his sagacity and fertility of resource appear in so strong a light as in the second book of the *Principia*, which is almost wholly occupied by this problem. The celebrated mathematician John Bernoulli engaged in it as the finest opportunity of displaying his superiority. A mistake committed by Newton in his attempt to a solution was matter of triumph to him; and the whole of his performance, though a piece of elegant and elaborate geometry, is greatly hurt by his continually bringing this mistake, which is a mere trifle, into view. The difficulty of the subject is so great, that subsequent mathematicians seem to have kept aloof from it; and it has been entirely overlooked by the many voluminous writers who have treated professedly on military projectiles. They have spoken indeed of the resistance of the air as affecting the flight of shot, but have

Resistance of air in gunnery.

saved themselves from the task of investigating this effect (a task to which they were unequal), by supposing that it was not so great as to render their theories and practical deductions very erroneous. Mr. Robins was the first who seriously examined the subject. He showed, that even the Newtonian theory, which had been corrected, but not in the smallest degree improved or extended in its principles, was sufficient to show that the path of a cannon ball could not resemble a parabola. Even this theory showed that the resistance was more than eight times the weight of the ball, and should produce a greater deviation from the parabola than the parabola deviated from a straight line.

Ignorance in this respect of writers on artillery.

This simple but singular observation was a strong proof how faulty the professed writers on artillery had been, in rather amusing themselves with elegant but useless applications of easy geometry, than in endeavouring to give their readers any useful information. He added, that the difference between the ranges by the Newtonian theory and by experiment was so great, that the resistance of the air must be vastly superior to what that theory supposed. It was this which suggested to him the necessity of experiments to ascertain this point. We have seen the result of these experiments in moderate velocities; and that they were sufficient for calling the whole theory in question, or at least for rendering it useless. It became necessary therefore to settle every point by means of a direct experiment. Here was a great difficulty. How shall we measure either these great velocities which are observed in the motions of cannon-shot, or the resistances which these enormous velocities occasion? Mr. Robins had the ingenuity to do both. The method which he took for measuring the velocity of a musket-ball was quite original; and it was susceptible of great accuracy. We have already given an account of it under the article GUNNERY. Having gained this point, the other was not difficult. In the moderate velocities he had determined the resistances by the forces which balanced them, the weights which kept the resisted body in a state of uniform motion. In the great velocities, he proposed to determine the resistances by their immediate effects, by the retardations which they occasioned. This was to be done by first ascertaining the velocity of the ball, and then measuring its velocity after it had passed through a certain quantity of air. The difference of these velocities is the retardation, and the proper measure of the resistance; for, by the initial and final velocities of the ball, we learn the time which was employed in passing through this air with the medium velocity. In this time the air's resistance diminished the velocity by a certain quantity. Compare this with the velocity which a body projected directly upwards would lose in the same time by the resistance of gravity. The two forces must be in the proportion of their effects. Thus we learn the proportion of the resistance of the air to the weight of the ball. It is indeed true, that the time of passing through this space is not accurately had by taking the arithmetical medium of the initial and final velocities, nor does the resistance deduced from this calculation accurately correspond to this mean velocity; but both may be accurately found by the experiment by a very troublesome computation, as is shown in the fifth and sixth propositions of the second book of Newton's *Principia*. The difference between the quantities thus found and those deduced from the simple process is quite trifling, and far within the limits of accuracy attainable in experiments of this kind; it may therefore be safely neglected.

Mr. Robins's experiments on this subject.

Mr. Robins made many experiments on this subject; but unfortunately he has published only a very few, such as were sufficient for ascertaining the point he had in view. He intended a regular work on the subject, in which the gradual variations of resistance corresponding to different velocities should all be determined by experiment; but he was then newly engaged in an important and laborious employment, as chief engineer to the East India Company, in whose service he went out to India, where he died in less than two years. It is to be regretted that no person has prosecuted these experiments. It would be neither laborious nor difficult, and would add more to the improvement of artillery than any thing that has been done since Mr. Robins's death, if we except the prosecution of his experiments on the initial velocities of cannon-shot by Dr. Charles Hutton, royal professor at the Woolwich Academy. It is to be hoped that this gentleman, after having with such effect and success extended Mr. Robins's experiments on the initial velocities of musket-shot to cannon, will take up this other subject, and thus give the art of artillery all the scientific foundation which it can receive in the present state of our mathematical knowledge. Till then we must content ourselves with the practical rules which Robins has deduced from his own experiments. As he has not given us the mode of deduction, we must compare the results with experiment. He has indeed given a very extensive comparison with the numerous experiments made both in Britain and on the continent; and the agreement is very great. His learned commentator Euler has been at no pains to investigate these rules, and has employed himself chiefly in detecting errors, most of which are supposed, because he takes for a finished work what Mr. Robins only gives to the public as a hasty but useful sketch of a new and very difficult branch of science.

Resistance of air in gunnery.

General results.

The general result of Robins's experiments on the retardation of musket shot is, that although in moderate velocities the resistance is so nearly in the duplicate proportion of the velocities that we cannot observe any deviation, yet in velocities exceeding 200 feet per second the retardations increase faster, and the deviation from this rate increases rapidly with the velocity. He ascribes this to the causes already mentioned, viz. the condensation of the air before the ball and to the rarefaction behind, in consequence of the air not immediately occupying the space left by the bullet. This increase is so great, that if the resistance to a ball moving with the velocity of 700 feet in a second be computed on the supposition that the resistance observed in moderate velocities is increased in the duplicate ratio of the velocity, it will be found hardly one-third part of its real quantity. He found, for instance, that a ball moving through 1670 feet in a second lost about 125 feet per second of its velocity in passing through 50 feet of air. This it must have done in the $\frac{1}{32}$ of a second, in which time it would have lost one foot if projected directly upwards; from which it appears that the resistance was about 125 times its weight, and more than three times greater than if it had increased from the resistance in small velocities in the duplicate ratio of the velocities. He relates other experiments which show similar results. See GUNNERY.

The discussions of mathematicians not easily applied.

The first mathematicians of Europe have employed themselves in improving the theory of the motion of bodies in a resisting medium; but their discussions are such as few artillerists can understand. The problem can only be solved by approximation, and this by the quadrature of very complicated curves. They have not been able therefore to deduce from them any practical rules of easy application, and have been obliged to compute tables suited to different cases. Of these performances, that of the Chevalier Borda, in the *Memoirs of the Academy of Sciences* for 1769, seems the best adapted to military readers, and the tables are undoubtedly of considerable use; but it is not too much to say, that the simple rules of Mr. Robins are of as much service, and are more easily remembered; besides, it must be observed, that the nature of military service does not give room for the application of any very precise rule. The only advantage that we can derive from a perfect theory would be an improvement in the construction of pieces of ordnance, and a more judicious appropriation of certain velocities to cer-

Undulation of air.

tain purposes. The service of a gun or mortar must always be regulated by the eye.

Undulation of air.

There is another motion of which air and other elastic fluids are susceptible, viz. an internal vibration of their particles, or undulation, by which any extended portion of air is distributed into alternate parcels of condensed and rarefied air, which are continually changing their condition without changing their places. By this change the condensation which is produced in one part of the air is gradually transferred along the mass of air to the greatest distances in all directions. It is of importance to have some distinct conception of this motion. It is found to be by this means that distant bodies produce in us the sensation of sound. Sir Isaac Newton treated this subject with his accustomed ingenuity, and has given us a theory of it in the end of the second book of his *Principia*. This theory has been objected to with respect to the conduct of the argument, and other explanations have been given by the most eminent mathematicians. Though they appear to differ from Newton's, their results are precisely the same; but, on a close examination, they differ no more than John Bernoulli's theorem of centripetal forces differs from Newton's, viz. the one being expressed by geometry and the other by literal analysis. The celebrated Lagrange reduces Newton's investigation to a tautological proposition or identical equation; but Mr. Young of Trinity College, Dublin, has, by a different turn of expression, freed Newton's method from this objection.

This has een used o explain variety of atural henomena.

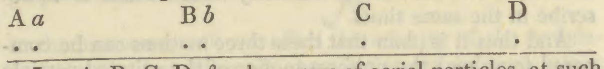
But since Newton published this theory of aerial undulations, and of their propagation along the air, and since the theory has been so corrected and improved as to be received by the most accurate philosophers as a branch of natural philosophy susceptible of rigid demonstration, it has been freely resorted to by many writers on other parts of natural science, who did not profess to be mathematicians, but made use of it for explaining phenomena in their own line on the authority of the mathematicians themselves. Learning from them that this vibration, and the *quaquaversum* propagation of the pulses, were the necessary properties of an elastic fluid, and that the rapidity of this propagation had a certain assignable proportion to the elasticity and density of the fluid, they freely made use of these concessions, and have introduced elastic vibrating fluids into many facts, where others would suspect no such thing, and have attempted to explain by their means many abstruse phenomena of nature. Æthers are everywhere introduced, endued with great elasticity and tenuity. Vibrations and pulses are supposed in this æther, and these are offered as explanations. The doctrines of animal spirits and nervous fluids, and the whole mechanical system of Hartley, by which the operations of the soul are said to be explained, have their foundation in this theory of aerial undulations. If these fancied fluids, and their internal vibrations, really operate in the phenomena ascribed to them, any explanation that can be given of the phenomena from this principle must be nothing else then showing that the legitimate consequences of these undulations are similar to the phenomena; or, if we are no more able to see this last step than in the case of sound, (which we know to be *one* consequence of the aerial undulations, although we cannot tell how), we must be able to point out, as in the case of sound, certain constant relations between the general laws of these undulations and the general laws of the phenomena. It is only in this way that we think ourselves entitled to say that the aerial undulations are causes, though not the only causes, of sound; and it is because there is no such relation, but, on the contrary, a total dissimilarity, to be observed between the laws of elastic undulations and the laws of the propagation of light, that we assert with confidence that ethereal undulations are not the causes of vision.

Undulation of air.

Explanations of this kind suppose, therefore, in the first place, that the philosopher who proposes them understands precisely the nature of these undulations; in the next place, that he makes his reader sensible of those circumstances of them which are concerned in the effect to be explained; and, in the third place, that he makes the reader understand how this circumstance of the vibrating fluid is connected with the phenomenon, either by showing it to be its mechanical cause, as when the philosopher explains the resounding of a musical chord to a flute or pipe which gave the same tone; or by showing that this circumstance of the undulation always accompanies the phenomenon, as when the philosopher shows that 233 vibrations of air in a second, in whatever manner or by whatever cause they are produced, always are followed by the sensation of the tone C in the middle of the harpsichord.

How elastic differ from unelastic fluids.

We propose now to give some account of the motion of elastic fluids; and the first thing incumbent on us is to show how these fluids differ from the unelastic in the propagation of any agitation of their parts. When a long tube is filled with water, and any one part of it pushed out of its place, the whole is instantly moved like a solid mass. But this is not the case with air. If a door be suddenly shut, the window at the farther end of a long and close room will rattle; but some time will elapse between the shutting of the door and the motion of the window. If some light dust be lying on a braced drum, and another be violently beat at a little distance from it, an attentive observer will see the dust dance up from the parchment; but this will be at the instant he hears the sound of the stroke on the other drum, and a sensible time after the stroke. Many such familiar facts show that the agitation is gradually communicated along the air; and therefore that when one particle is agitated by any sensible motion, a finite time, however small, must elapse before the adjoining particle is agitated in the same manner. This would not be the case in water if water be perfectly incompressible. We think that this may be made intelligible with very little trouble.



Let A, B, C, D, &c. be a row of aerial particles, at such distances that their elasticity just balances the pressure of the atmosphere; and let us suppose (as is deducible from the observed density of air being proportional to the compressing force) that the elasticity of the particles, by which they keep each other at a distance, is as their distances inversely. Let us farther suppose that the particle A has been carried, with an uniform motion, to a by some external force. It is evident that B cannot remain in its present state; for being now nearer to a than to C, it is propelled towards C by the excess of the elasticity of A above the natural elasticity of C. Let E be the natural elasticity of the particles, or the force corresponding to the distance BC or BA, and let F be the force which impels B towards C, and let f be the force exerted by A when at a. We have

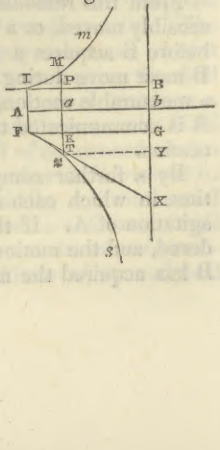
$$\mathrm{E} : f = \mathrm{B}a : \mathrm{BC} = \mathrm{B}a,\ \mathrm{BA};$$

$$\text{and } \mathrm{E} : f - \mathrm{E} = \mathrm{B}a : \mathrm{BA} - \mathrm{B}a = \mathrm{B}a : \mathrm{A}a;$$

$$\text{or } \mathrm{E} : \mathrm{F} = \mathrm{B}a : \mathrm{A}a.$$

Now, in fig. 81, let ABC be the line joining three particles, to which draw FG, PH parallel, and IAF, HBG perpendicular. Take IF or HG to represent the elasticity corresponding to the distance AB. Let the particle A be supposed to have been carried with an uniform motion to a by some external force, and draw RaM perpendicular to RG; and make FI : RM = Ba : BA. We shall then have FI : PM = Ba : Aa; and PM will represent the force

Fig. 81.



Undulation of air.

with which the particle B is urged towards C. Suppose this construction to be made for every point of the line AB, and that a point M is thus determined for each of them, mathematicians know that all these points M lie in the curve of a hyperbola, of which FG and GH are the asymptotes. It is also known by the elements of mechanics, that since the motion of A along AB is uniform, A*a* or IP may be taken to represent the time of describing A*a;* and that the area IPM represents the whole velocity which B has acquired in its motion towards C when A has come to *a*, the force urging B being always as the portion PM of the ordinate.

Take GX of any length in HG produced, and let GX represent the velocity which the uniform action of the natural elasticity IF could communicate to the particle B during the time that A would uniformly describe AB. Make GX to GY as the rectangle IFGH to the hyperbolic space IFRM, and draw YS cutting MR produced in S, and draw FX cutting MR in T. It is known to the mathematicians that the point S is in a curve line FS*s*, called the *logarithmic curve;* of which the leading property is, that any line RS parallel to GX is to GX as the rectangle IFGH is to the hyperbolic space IFRM, and that FX touches the curve in F.

This being the case, it is plain, that because RT increases in the same proportion with FR, or with the rectangle IFRP, and RS increases in the proportion of the space IFRM, TS increases in the proportion of the space IPM. Therefore TS is proportional to the velocity of B when A has reached *a*, and RT is proportional to the velocity which the uniform action of the natural elasticity would communicate to B in the same time. Then since FT is as the time, and TS is as the velocity, the area FTS will be as the space described by B, urged by the variable force PM; while A, urged by the external force, describes A*a;* and the triangle FRT will represent the space which the uniform action of the natural elasticity would cause B to describe in the same time.

And thus it is plain that these three motions can be compared together: the uniform motion of the agitated particle A, the uniformly accelerated motion which the natural elasticity would communicate to B by its constant action, and the motion produced in B by the agitation of A. But this comparison, requiring the quadrature of the hyperbola and logarithmic curve, would lead us into most intricate and tedious computations. Of these we need only give the result, and make some other comparisons which are palpable.

Let A*a* be supposed indefinitely small in comparison of AB. The space described by A is therefore indefinitely small; but in this case we know that the ratio of the space FRT to the rectangle IFRP is indefinitely small. There is therefore no comparison between the agitation of A by the external force, and the agitation which natural elasticity would produce on a single particle in the same time, the last being incomparably smaller than the first. And this space FRT is incomparably greater than FTS; and therefore the space which B would describe by the uniform action of the natural elasticity is incomparably greater than what it would describe in consequence of the agitation of A.

From this reasoning we see evidently that A must be sensibly moved, or a finite or measurable time must elapse before B acquires a measurable motion. In like manner, B must move during a measurable time before C acquires a measurable motion, &c.; and therefore the agitation of A is communicated to the distant particles in gradual succession.

By a further comparison of these spaces we learn the time in which each succeeding particle acquires the very agitation of A. If the particles B and C only are considered, and the motion of C neglected, it will be found that B has acquired the motion of A a little before it has described one-third of the space described by A; but if the motion of C be considered, the acceleration of B must be increased by the retreat of C, and B must describe a greater space in proportion to that described by A. By computation it appears, that when both B and C have acquired the velocity of A, B has described nearly one-half of A's motion, and C more nearly one-third. Extending this to D, we shall find that D has described still more nearly one-fourth of A's motion. And from the nature of the computation it appears that this approximation goes on rapidly; therefore, supposing it accurate from the very first particle, it follows from the equable motion of A, that each succeeding particle moves through an equal space in acquiring the motion of A.

The conclusion which we must draw from all this is, that when the agitation of A has been fully communicated to a particle at a *sensible* distance, the intervening particles, all moving forward with a common velocity, are equally compressed as to sense, except a very few of the first particles; and that this communication, or this propagation of the original agitation, goes on with an uniform velocity.

These computations need not be attended to by such as do not wish for an accurate knowledge of the precise agitation of each particle. It is enough for such readers to see clearly that time *must* escape between the agitation of A and that of a distant particle; and this is abundantly manifest from the incomparability (excuse the term) of the nascent rectangle IFRP with the nascent triangle FRT, and the incomparability of FRT with FTS.

Newton's demonstration on this subject.

What has now been shown of the communication of any sensible motion A *a* must hold equally with respect to any change of this motion. Therefore if a tremulous motion of a body, such as a spring or bell, should agitate the adjoining particle A by pushing it forward in the direction AB, and then allowing it to come back again in the direction BA, an agitation similar to this will take place in all the particles of the row one after the other. Now if this body vibrate according to the law of motion of a pendulum vibrating in a cycloid, the neighbouring particle of air *will of necessity* vibrate in the same manner; and then Newton's demonstration in the article Acoustics needs no apology. Its only deficiency was, that it *seemed* to prove that this *would be* the way in which every particle would of necessity vibrate; which is not true, for the successive parcels of air will be differently agitated according to the original agitation. Newton only wants to prove the uniform propagation of the agitations, and he selects that form which renders the proof easiest. He proves, in the most unexceptionable manner, that if the particles of a pulse of air are really moving like a cycloidal pendulum, the forces acting on each particle, in consequence of the compression and dilatation of the different parts of the pulse, are precisely such as are necessary for continuing this motion, and therefore no other forces are required. Then since each particle in a certain part of its path, is moving in a certain direction, and with a certain velocity, and urged by a determined force, it *must* move in that very manner. The objection started by John Bernoulli against Newton's demonstration of the elliptical motion of a body urged by a force in the inverse duplicate ratio of the distance from the focus, is precisely the same with the objection against Newton's demonstration of the progress of aerial undulations, and is equally futile.

It must, however, be observed, that Newton's demonstration proceeds on the supposition that the linear agitations of a particle are incomparably smaller than the extent of an undulation. This is not strictly the case in any instance, and in many it is far from being true. In a pretty strong twang of a harpsichord wire, the agitation of a particle may be near the 50th part of the extent of the undulation. This must disturb the regularity of the motion, and cause the ndulation of air.

agitations in the remote undulations to differ from those in the first pulse. In the explosion of a cannon, the breaking of an exhausted bottle, and many instances which may be given, the agitations are still greater. The commentators on Newton's *Principia*, Le Sueur and Jacquier, have shown, and Euler more clearly, that when the original agitations are very violent, the particles of air will acquire a subordinate vibration compounded with the regular cycloidal vibration, and the progress of the pulses will be somewhat more rapid; but the intricacy of the calculus is so great, that they have not been able to determine with any tolerable precision what the change of velocity will be.

onfirmed experi- ents on unds.

All this, however, is fully confirmed by experiment on sounds. The sound of a cannon at 10 or 20 miles distance does not in the least resemble its sound when near. In this case it is a loud instantaneous crack, to which we can assign no musical pitch. At a distance, it is a grave sound, of which we can tell the note; and it begins softly, swells to its greatest loudness, and then dies away growling. The same may be said of a clap of thunder, which we know to be a loud snap of still less duration. It is highly probable that the appreciable tones which those distant sounds afford are produced by the continuance of these subordinate vibrations which are added together and fortified in the successive pulses, though not perceptible in the first, in a way somewhat resembling the resonance of a musical chord. Newton's explanation gathers evidence therefore from this circumstance. And we must further observe, that all elastic bodies tremble or vibrate almost precisely as a pendulum swinging in a cycloid, unless their vibrations are uncommonly violent; in which case they are quickly reduced to a moderate quantity by the resistance of the air. The only very loud sounds which we can produce in this way are from great bells; and in these the utmost extent of the vibration is very small in comparison with the breadth of the pulse. The velocity of these sounds has not been compared with that of cannon, or perhaps it would be found less, and an objection against Newton's determination removed. He gives 969 feet per second, (experiment 1142.)

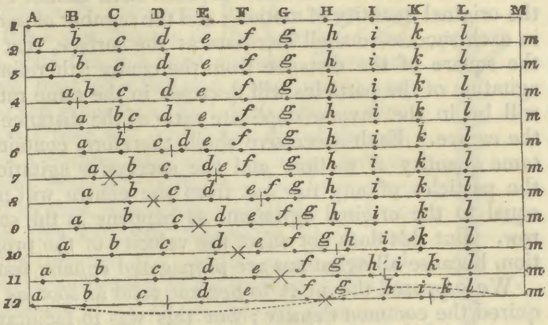
he agita- on in the ccessive ulses pro- ably as- umes a cy- loidal form.

But it is also very probable, that in the propagation through the air, the agitation gradually and rapidly approaches to this regular cycloidal form in the successive pulses, in the same way as we observe that whatever is the form of agitation in the middle of a smooth pond of water, the spreading circles are always of one gentle form without asperities. In like manner, into whatever form we throw a stretched cord by the twang which we give it, it almost immediately makes smooth undulations, keeping itself in the shape of an elongated trochoid. Of this last we can demonstrate the necessity, because the case is simple. In the wave, the investigation is next to impossible; but we see the fact. We may therefore presume it in air. And accordingly we know that any noise, however abrupt and jarring near at hand, is smooth at a distance. Nothing is more rough and harsh than the scream of a heron; but at half a mile's distance it is soft. The ruffle of a drum is also smooth at a distance.

Undulation of air.

Fig. 82, shows the successive situations of the particles of a row. Each line of the figure shows the same particles marked with the same letters; the first particle *a* being supposed to be removed successively from its quiescent situation and back to it again. The mark × is put on that part of each line where the agitated particles are at their natural distances, and the air is of the natural density. The mark | is put where the air is most of all compressed, and : where it is most of all dilated; the curve line drawn through the lowest line of the figure is intended to represent the density in every point, by drawing ordinates to it from the straight line. The ordinates below the line indicate a rarity, and those above the line a density, greater than common. It appears that when *a* has come back to its natural situation, the part of greatest density is between the particles *i* and *k*, and the greatest rarity between *c* and *d*.

Fig. 82.

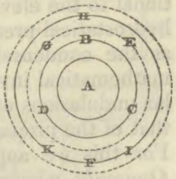


We have only to add, that the velocity of this propagation depends on the elasticity and density of the fluid. If these vary in the same proportion, that is, if the fluid has its elasticity proportional to its density, the velocity will remain the same. If the elasticity or density alone be changed, the velocity of the undulations will change in the direct subduplicate ratio of the elasticity and the inverse subduplicate ratio of the density; or should the elasticity be quadrupled, the quantity of motion produced by it in any given time will be quadrupled. This will be the case if the velocity be doubled; for there would then be double the number of particles doubly agitated. Should the density be quadrupled, the elasticity remaining the same, the quantity of motion must remain the same. This will be the case if the velocity be reduced to one half; for this will propagate half the agitation to half the distance, which will communicate it to twice the number of particles, and the quantity of motion will remain the same. The same may be said of other proportions, and therefore $V=\frac{\sqrt{E}}{\sqrt{D}}$. Therefore a change in the barometer will not affect the velocity of the undulations in air; but they will be accelerated by heat, which diminishes its density, or increases its elasticity. The velocity of the pulses in inflammable air must be at least thrice as great, because its density is but one-tenth of that of air when the elasticity of both are the same.

Further considera- tion of aerial pulses.

Let us now attend a little to the propagation of aerial pulses as they really happen; for this hypothesis of a single row of particles is nowhere to be observed. Suppose a sphere A, fig. 83, filled with condensed air, and that the vessel which contains it is suddenly annihilated. The air must expand to its natural dimensions, suppose BCD. But it cannot do this without pressing aside the surrounding air. We have seen that in any single row of particles this cannot be at once diffused to a distance, but must produce a condensation in the air adjoining; which will be gradually propagated to a distance. Therefore this sphere BCD of the common density will form round it a shell, bounded by EFG, of condensed air. Suppose that at this instant the inner air BCD becomes solid. The shell of condensed air can expand only outwards. Let it expand till it is of the common density, occupying the shell HIK. This expansion must, in like manner, produce a shell of condensed air without it; and at this instant let HIK become solid. The surrounding shell of condensed air can expand only outward, condensing another shell without it. It is plain that this must go on continually, and the central agitation will be gradually propagated to a distance in all directions. But, in this process, it is not the same numerical particles that go to a distance. Those of the original

Fig. 83.



Undulation of air.

sphere go no further than BCD, those of the next shall go no further than HIK, &c. Further, the expansion outwards of any particle will be more moderate as the diffusion advances; for the whole motion of each shell cannot exceed the original quantity of motion; and the number of particles in each successive shell increases as the surface, that is, as the square of the distance from the centre; therefore the agitation of the particles will decrease in the same ratio, or will be in the inverse duplicate ratio of the distance from the centre. Each successive shell, therefore, contains the same quantity of motion, and the successive agitations of the particles of any row out from the centre will not be equal to the original agitation, as happens in the solitary row. But this does not affect the velocity of the propagation, because all agitations are propagated equally fast.

We supposed the air A to become solid as soon as it acquired the common density; but this was to facilitate the conception of the diffusion. It does not stop at this bulk; for while it was denser it had a tendency to expand. Therefore each particle has attained this distance with an accelerated motion. It will, therefore, continue this motion like a pendulum that has passed the perpendicular, till it is brought to rest by the air without it; and it is now rarer than common air, and collapses again by the greater elasticity of the air without it. This outward air, therefore, in regaining its natural density, must expand both ways. It expands towards the centre, following the collapsing of the air within it; and it expands outwards, condensing the air beyond it. By expanding inwards, it will again condense the air within it, and this will again expand; a similar motion happens in all the outward shells; and thus there is propagated a succession of condensed and rarefied shells of air, which gradually swell to the greatest distance.

Application of the fact of dropping a pebble into water.

It may be demonstrated, that when the central air has for the second time acquired the natural density, it will be at rest, and be disturbed no more; and that this will happen to all the shells in succession. But the demonstration is much too intricate for this place; and we must be contented with pointing out a fact perfectly analogous. When we drop a small pebble into water, we see it produce a series of circular waves, which go along the surface of smooth water to a great distance, becoming more and more gentle as they recede from the centre; and the middle, where the agitation was first produced, remains perfectly smooth, and this smoothness extends continually; that is, each wave when brought to a level remains at rest. Now these waves are produced and propagated by the depression and elevation made at the centre. The elevation tends to diffuse itself; and the force with which each particle of water is actuated is a force acting directly up and down, and is proportional to the elevation or depression of the particle. This hydrostatical pressure operates precisely in the same way as the condensation and rarefaction of the air; and the mathematical investigation of the propagation of the circular undulations on smooth water is similar in every step to that of the propagation of the spherical waves in still air. For this we appeal to Newton's *Principia*, or to Euler's *Opuscula*, where he gives a very beautiful investigation of the velocity of the aerial pulses; and to some memoirs of Lagrange in the collections of the academies of Berlin and Turin. These two last authors have made the investigation as simple as seems possible, and have freed it from every objection which can be stated against the geometrical one of their greater teacher Newton.

The waves of water are useful in explaining those of air.

Having said this much respecting the similarity between the waves on water and the aerial undulations, we shall have recourse to them, as affording us a very sensible object to represent many affections of the other which it would be extremely difficult to explain. We neither see nor feel the aerial undulations; and they behoved, therefore, to be described very abstractedly and imperfectly. In the watery wave there is no permanent progressive motion of the water from the centre. Throw a small bit of cork on the surface, and it will be observed to popple up and down without the least motion outwards. In like manner, the particles of air are only agitated a very little outwards and inwards, which motion is communicated to the particles beyond them, whilst they themselves come to rest, unless agitated afresh; and this agitation of the particles is inconceivably small. Even the explosion of a cannon at no great distance will but gently agitate a feather, giving it a single impulse outwards, and immediately after another inwards or towards the cannon. When a harpsichord wire is forcibly twanged at a few feet distance, the agitation of the air is next to insensible. It is not, however, nothing; and it differs from that in a watery wave by being *really* outwards and inwards. In consequence of this, when the condensed shell reaches an elastic body, it impels it slightly. If its elasticity be such as to make it acquire the opposite shape at the instant that the next agitation and condensed shell of air touches it, its agitation will be doubled, and a third agitation will increase it, and so on, till it acquire the agitation competent to that of the shell of air which reaches it, and it is thrown into sensible vibration, and gives a sound extremely faint indeed, because the agitation which it acquires is that corresponding to a shell of air considerably removed from the original string. Hence it happens that a musical chord, pipe, or bell, will cause another to resound, whose vibrations are isochronous with its own; or if the vibrations of the one coincides with every second, or third, or fourth, &c. of the other; just as we can put a very heavy pendulum into sensible motion by giving it a gentle puff with the breath at every vibration, or at every second, third, or fourth, &c. A drum struck in the neighbourhood of another drum will agitate it very sensibly; for here the stroke depresses a very considerable surface, and produces an agitation of a considerable mass of air; it will even agitate the surface of stagnant water. The explosion of a cannon will even break a neighbouring window. The shell of condensed air which comes against the glass has a great surface and a great agitation; the best security in this case is to throw up the sash; this admits the condensed air into the room, which acts on the inside of the window, balancing part of the external impulse.

Waves of air and of water in some respects similar.

It is demonstrated in every elementary treatise of natural philosophy, that when a wave on water meets any plane obstacle, it is reflected by it from a centre equally removed behind the obstacle; that waves radiating from the focus of a parabola are reflected in waves perpendicular to its axis; that waves radiating from one focus of an ellipse are made to converge to the other focus, &c. All this may be affirmed of the aerial undulations; that when part of a wave gets through a hole in the obstacle, it becomes the centre of a new series of a waves; that waves bend round the extremities of an obstacle; all this happens in the aerial undulations. And lastly, that when the surface of water is thrown into regular undulations by one agitation, another agitation in another place will produce other regular waves, which will cross the former without disturbing them in the smallest degree. The same thing happens in air; and experiments may be made on water which will illustrate in the most perfect manner many other affections of the aerial pulses, which we should otherwise conceive very imperfectly. We would recommend to our curious readers to make some of these experiments in a large vessel of milk. Take a long and narrow plate of lead, which, when set on the bottom of the vessel, will reach above the surface of the milk; bend this plate into a parabola, elliptical, or other curve. Make the undulations by dropping milk on the focus from a small pipe, which will cause the agitations to succeed with rapidity, and then all that we have said will be most distinctly seen, and the experiment will be

Effects of he pres- ure of the air.

very amusing and instructive, especially to the musical reader.

We shall now proceed to explain a number of natural appearances, depending on the pressure and the elasticity of the air; appearances not sufficiently general, or too complicated for the purposes of argument, whilst we were employed in the investigation of these properties, but too important to be passed over in silence.

he pres- ure of the ir occa- ions the ohesion of wo sur- aces, &c.

It is owing to the pressure of the atmosphere that two surfaces which accurately fit each other cohere with such force. This is a fact familiarly known to the glass-grinders, polishers of marble, &c. A large lens or speculum, ground on its tool till it becomes very smooth, requires more than any man's strength to separate it directly from the tool. If the surface is only a square inch, it will require fifteen pounds to separate them perpendicularly, though a very moderate force will make them slide along each other. But this cohesion is not observed unless the surfaces are wetted or smeared with oil or grease; otherwise the air gets between them, and they separate without any trouble. That this cohesion is owing to the atmospheric pressure, is evident from the ease with which the plates may be separated in an exhausted receiver. To the same cause we must ascribe the very strong adhesion of snails, periwinkles, limpets, and other univalve shells, to the rocks. The animal forms the rim of its shell, so as to fit the shape of the rock to which it intends to cling. It then fills its shell, if not already filled by its own body, with water. In this condition it is evident that we must act with a force equal to fifteen pounds for every square inch of touching surface before we can detach it. This may be illustrated by filling a drinking-glass to the brim with water, and having covered it with a piece of thin wet leather, whelm it on a table, and then try to pull it straight up; which will require a considerable force. But if we expose a snail adhering to a stone in the exhausted receiver, we shall see it drop off by its own weight. In the same manner do the remora, the polypus, the lamprey, and many other animals, adhere with such firmness. Boys frequently amuse themselves by pulling out large stones from the pavement by means of a circle of stiff wetted leather fastened to a string. It is owing to the same cause that the bivalve shell fishes keep themselves so firmly shut. We think the muscular force of an oyster prodigious, because it requires such force to open it; but if we grind off a bit of the convex shell, so as to make a hole in it, though without hurting the fish in the smallest degree, it opens with great ease, as it does also *in vacuo*.

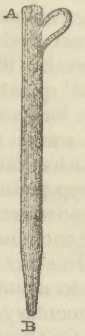
ther ef- cts of the ressure of e air.

The pressure of the air, operating in this way, contributes much to the cohesion of bodies, where we do not suspect its influence. The tenacity of our mortars and cements would frequently be ineffectual without this assistance. It is owing to the pressure of the atmosphere that a cask will not run by the cock unless a hole be opened in some other part of the cask. If the cask is not quite full, some liquor indeed will run out, but it will stop as soon as the diminished elasticity of the air above the liquor is in equilibrio, together with the liquor, with the atmospheric pressure. In like manner, a teapot must have a small hole in its lid to ensure its pouring out the tea. If indeed the hole in the cask is of large dimensions, it will run without any other, because air will get in at the upper side of the hole while the liquor runs out by the lower part of it. On the same principle depends the performance of an instrument used by the spirit-dealers for taking out a sample of their spirits. It consists of a long tinplate tube AB (fig. 84,) open a-top at A, and ending in a small hole at B. The end B is dipped into the spirits, which rises into the tube; then the thumb is clapt on the mouth A, and the whole is lifted out of the cask. The spirit remains in it till the thumb be taken off; it is then allowed to run into a glass for examination.

Effects of the pressure of the air.

Why frosts instantly occasion a scarcity of water.

Fig. 84.



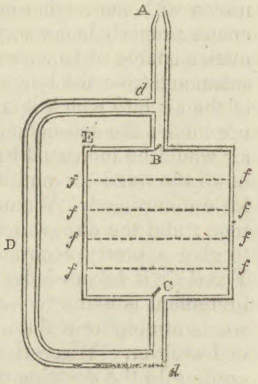
It seems principally owing to the pressure of the air that frosts immediately occasion a scantiness of water in our fountains and wells. This is erroneously accounted for, by supposing that the water freezes in the bowels of the earth. But this is a great mistake. The most intense frost of a Siberian winter would not freeze the ground two feet deep; but a very moderate frost will consolidate the whole surface of a country, and make it impervious to the air; especially if the frost has been preceded by rain, which has soaked the surface. When this happens, the water which was filtering through the ground is all arrested and kept suspended in its capillary tubes by the pressure of the air, in the very same manner as the spirits are kept suspended in the instrument just now described by the thumb's shutting the hole A. A thaw melts the superficial ice, and allows the water to run in the same manner as the spirits run when the thumb is removed.

The necessity of common air to animal life.

Common air is necessary for supporting the lives of most animals. If a small animal, such as a mouse or bird, be put under the receiver of an air-pump, and the air be exhausted, the animal will quickly be thrown into convulsions and fall down dead; if the air be immediately readmitted, the animal will sometimes revive, especially if the rarefaction has been briskly made, and has not been very great. We do not know that any breathing animal can bear the air to be reduced to one-fourth of its ordinary density, nor even one-third; nor have we good evidence that an animal will ever recover if the rarefaction is pushed very far, although continued for a very short time.

But the mere presence of the air is by no means sufficient for preserving the life of the animal; for it is found, that an animal shut up in a vessel of air cannot live in it for any length of time. If a man be shut up in a box, containing a wine hogshead of air, he cannot live in it much above an hour, and long before this he will find his breathing very unsatisfactory and uneasy. A gallon of air will support him about a minute. A box EF (fig. 85,) may be made, having a pipe AB inserted into its top, and fitted with a very light valve at B, opening upwards. This pipe sends off a lateral branch aD, dC, which enters the box at the bottom, and is also fitted with a light valve at C opening upwards. If a person breathe through the pipe, keeping his nostrils shut, it is evident that the air which he expires will not enter the box by the hole B, nor return through the pipe CDd; and by this contrivance he will gradually employ the whole air of the box. With this apparatus experiments can be made without any risk or inconveniency, and the quantity of air necessary for a given time of easy breathing may be accurately ascertained.

Fig. 85.



How the air of our atmosphere produces this effect, is a question which does not belong to mechanical philosophy to investigate or determine. We can, however, affirm, that it is neither the pressure nor the elasticity of the air which is immediately concerned in maintaining the animal functions. We know that we can live and breathe with perfect freedom on the tops of the highest mountains. The valley of Quito in Peru, and the country round Gondar in Abyssinia, are so far elevated above the surface of the ocean, that the pressure and the elasticity of the air are one-third less

Effects of the pressure of the air.

than in the low countries; yet these are populous and healthy places. And, on the other hand, we know, that when an animal has breathed in any quantity of air for a certain time without renewal, it will not only be suffocated, but another animal put into this air will die immediately. And we do not find either the pressure or elasticity of the air remarkably diminished; it is indeed diminished, but by a very small quantity. Restoring the former pressure and elasticity has not the smallest tendency to prevent the death of the animal; for an animal will live no longer under a receiver that has its mouth inverted on water, than in one set upon the pump-plate covered with leather. Now when the receiver is set on water, the pressure of the atmosphere acts completely on the included air, and preserves it in the same state of elasticity.

The nature of air that has been pired, altered.

In short, it is known that the air which has already served to maintain the animal functions has its chemical and alimentary properties completely changed, and is no longer fit for this purpose. So much of any mass of air as has really been thus employed is changed into what is called *fixed air* by Dr. Black, or *carbonic acid* by the chemists of the school of Lavoisier. Any person may be convinced of this by breathing or blowing through a pipe immersed in lime water. Every expiration will produce white clouds on the water, till all the lime which it contains is precipitated in the form of pure chalk. In this case we know that the lime has combined with the fixed air.

Hales's experiments.

The celebrated Dr. Stephen Hales made many experiments, with a view to clear the air from the noxious vapour which he supposed to be emitted from the lungs. He made use of the apparatus which we have been just now mentioning; and he put several diaphragms *ff*, *ff*, &c. of thin woollen stuff into the box, and moistened them with various liquids. He found nothing so efficacious as a solution of potash. We now understand this perfectly. If the solution is not already saturated with fixed air, it will take it up as fast as it is produced, and this will purify the air: a solution of caustic alkali therefore will have this effect till it is rendered quite mild.

How it comes to be changed.

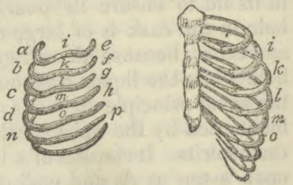
These experiments have been repeated, and varied in many circumstances, in order to ascertain whether this fixed air was really emitted by the lungs, or whether the inspired air was in part changed into fixed air by its combination with some other substance. This is a question which comes properly in our way, and which the doctrines of pneumatics enable us to answer. If the fixed air be emitted in substance from the lungs, it does not appear how a renewal of the air into which it is emitted is necessary, for this does not hinder the subsequent emission; and the bulk of the air would be increased by breathing in it, viz. by the bulk of all the fixed air emitted; but, on the contrary, it is a little diminished. We must therefore adopt the other opinion; and the discoveries in modern chemistry enable us to give a pretty accurate account of the whole process. Fixed air is acknowledged to be a compound, of which one ingredient is found to constitute about three-eighths of the whole atmospheric fluid, we mean vital air or the oxygen of Lavoisier. When this is combined with phlogiston, according to the doctrine of Stahl, or with charcoal, according to Lavoisier, the result is fixed air or carbonic acid. The change therefore which breathing makes on the air is the solution of this matter by vital air; and the use of air in breathing is the carrying off this noxious principle in the way of solution. When therefore the air is already so far saturated as not to dissolve this substance as fast as it is secreted, or must be secreted in the lungs, the animal suffers the pain of suffocation, or is otherwise mortally affected. Suffocation is not the only consequence; for we can remain for a number of seconds without breathing, and then we begin to feel the true pain of suffocation; but those who have been instantaneously struck down by an inspiration of fixed air, and afterwards recovered to life, complained of no such pain, and seemed to have suffered chiefly by a nervous affection. It is said, but we will not vouch for the truth of it, that a person may safely take a full inspiration of fixed air, if the passages of the nose be shut; and that unless these nerves are stimulated by the fixed air, it is not instantaneously mortal. But these are questions out of our present line of inquiry. They belong to physiology, and are treated of in other places of this work. Our business is to explain in what manner the pressure and elasticity of the air, combined with the structure and mechanism of the body, operate in producing this necessary secretion and removal of the matter discharged from the lungs in the act of breathing.

Effects of the pressure of the air.

It is well ascertained, that the secretion is made from the mass of blood during its passage through the lungs. The blood delivered into the lungs is of a dark blackish colour, and is there changed into a florid red. In the lungs it is exposed to the action of the air in a prodigiously extended surface; for the lungs consist of an inconceivable number of small vessels or bladders, communicating with each other and with the windpipe. These are filled with air in every inspiration. These vessels are everywhere in contact with minute blood-vessels. The blood does not *in toto* come into immediate contact with the air; and it would seem that it is only the thin serous part of it which is acted on by the air at the mouths of the vessels or pores, where it stands by capillary attraction. Dr. Priestley found, that venous blood inclosed in thin bladders and other membranes was rendered florid by keeping the bladders in contact with abundance of pure vital air. We know also, that breath is moist or damp, and must have acquired this moisture in the lungs. It is immaterial whether this secretion of water or lymph, as the anatomists call it, be furnished by mere exudation through simple pores, or by a vascular and organic secretion; in either case, some ingredient of the blood comes in contact with air in the lungs, and there unites with it. This is farther confirmed, by observing, that all breathing animals are warmer than the surrounding medium, and that by every process in which fixed air is formed from vital air, heat is produced. Hence this solution in air of something from the blood has been assigned by many as the source of animal heat. We touch on these things in a very transitory way in this place, only to prove that, for the support of animal life, there must be a very extensive application of the air to the blood, and that this is made in the lungs.

The question under consideration here is, How is this brought about by the weight and elasticity of the air? The answer is, it is done in two ways; by the action of the muscles of the ribs, and by the action of the diaphragm and other muscles of the abdomen. The thorax or chest is a great cavity, completely filled by the lungs. The sides of this cavity are formed by the ribs. These are crooked or arched, and each is moveable round its two ends, one of them being inserted into the vertebra of the back, and the other into the sternum or breast-bone. The rib turns in a manner resembling the handle of a drawer. The inspection of fig. 86 will illustrate this matter a little. Suppose the curves *a c e*, *b k f*, *c l g*, &c. to represent the ribs moveable round the extremities. Each succeeding rib is more bent than the one above it, and this curvature is both in the vertical and horizontal direction. Suppose each so broad as to project a little over its inferior like the tiles of a roof. It is evident, that if we take the lower one by its middle, and draw it out a little, moving it round the line *np*, it will bring out the next *dmh* along with it. Also, because the dis-

Fig. 86.

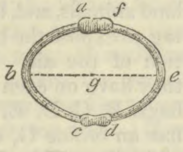


Effects of the pressure of the air.

tance of the middle point o from the axis of motion np is greater than the distance of m from the axis dh, and because o will therefore describe a portion of a larger circle than m does, the rib nop will slide up a little under the rib dmh, or the rib dmh will overlap nop a little more than before; the distance om will therefore be diminished. The same must happen to all the superior ribs; but the change of distance will be less and less as we go upwards. Now, instead of this great breadth of the ribs overlapping each other, suppose each inferior rib connected with the one above it by threads or fibres susceptible of contraction at the will of man. The articulations e, a, of the first or upper rib with the spine and sternum are so broad and firm, that this rib can have little or no motion round the line ae; this rib therefore is as a fixture for the ends of all the contracting fibres: therefore, whenever the fibres which connect the second rib with the first rib contract, the second must rise a little, and also go outward, and will carry the lower ribs along with it; the third rib will still rise farther by the contraction of the muscles which connect it with the second, and so on; and thus the whole ribs are raised and thrown outward (and a little forward, because the articulation of each with the spine is considerably higher than that with the sternum), and the capacity of the thorax is enlarged by the contraction of its muscular covering. The direction of the muscular fibres is very oblique to the direction of the circular motion which it produces; from which circumstance it follows, that a very minute contraction of the muscles produces all the motion which is necessary. This indeed is not great; the whole motion of the lowest ribs is less than an inch in the most violent inspiration, and the whole contraction of the muscles of the twelve ribs does not exceed the eighth part of an inch, even supposing the intercostal muscles at right angles to the ribs; and being oblique, the contraction is still less. It would seem, that the intensity of the contractive power of a muscular fibre is easily obtained, but that the space through which it can be exerted is very limited; for in most cases nature places the muscles in situations of great mechanical disadvantage in this respect, in order to procure other conveniences.

But this is not the whole effect of the contraction of the intercostal muscles; since the compound action of the two sets of muscles, which cross each other from rib to rib like the letter X, is nearly at right angles to the rib, but is oblique to its plane, it tends to push the ribs closer on their articulations, and thus to press out the two pillars on which they are articulated. Thus, supposing $a\,f$ (fig. 87) to represent the section of one of the vertebræ of the spine, and $c\,d$ a section of the sternum, and $a\,b\,c$, $f\,e\,d$, two opposite ribs, with a lax thread $b\,e$ connecting them. If this thread be pulled upwards by the middle g till it is tight, it will tend to pull the points b and e nearer to each other, and to press the vertebra $a\,f$ and the sternum $c\,d$ outwards. The spine being the chief pillar of the body, may be considered as immoveable in the present instance. The sternum is sufficiently susceptible of motion for the present purpose. It remains almost fixed a-top at its articulation with the first rib, but it gradually yields below; and thus the capacity of the thorax is enlarged in this direction also. The whole enlargement of the diameters of the thorax during inspiration is very small, not exceeding the fiftieth part of an inch in ordinary cases. This is easily calculated. Its quiescent capacity is about two cubic feet, and we never draw in more than fifteen inches. Two spheres, one of which holds two cubic feet and the other two feet and fifteen inches, will not differ in diameter above the fiftieth part of an inch.

Fig. 87.



The other method of enlarging the capacity of the thorax is very different. It is separated from the abdomen by a strong muscular partition called the diaphragm, which is attached to firm parts all around. In its quiescent or relaxed state it is considerably convex upwards, that is, towards the thorax, rising up into its cavity like the bottom of an ordinary quart bottle, only not so regular in its shape. Many of its fibres tend from its middle to the circumference, where they are inserted into firm parts of the body. Now suppose these fibres to contract. This must draw down its middle, or make it flatter than before, and thus enlarge the capacity of the thorax.

Effects of the pressure of the air.

Physiologists are not well agreed as to the share which each of these actions has in the operation of enlarging the thorax. Many refuse all share of it to the intercostal muscles, and say that it is performed by the diaphragm alone. But the fact is, that the ribs are really observed to rise even while the person is asleep; and this cannot possibly be produced by the diaphragm, as these anatomists assert. Such an opinion shows either ignorance or neglect of the laws of pneumatics. If the capacity of the thorax were enlarged only by drawing down the diaphragm, the pressure of the air would compress the ribs, and make them descend. And the simple laws of mechanics make it as evident as any proposition in geometry, that the contraction of the intercostal muscles must produce an elevation of the ribs and enlargement of the thorax; and it is one of the most beautiful contrivances of nature. It depends much on the will of the animal what share each of these actions shall have. In general, the greatest part is done by the diaphragm; and any person can breathe in such a manner that his rib shall remain motionless; and, on the contrary, he can breathe almost entirely by raising his chest. In the first method of breathing, the belly rises during inspiration, because the contraction of the diaphragm compresses the upper part of the bowels, and therefore squeezes them outwards; so that an ignorant person would be apt to think that the breathing was performed by the belly, and that the belly is inflated with the air. The strait lacing of the women impedes the motion of the ribs, and changes the natural habit of breathing, or brings on an unnatural habit. When the mind is depressed, it is observed that the breathing is more performed by the muscles of the thorax; and a deep sigh is always made in this way.

These observations on the manner in which the capacity of the chest can be enlarged were necessary, before we can acquire a just notion of the way in which the mechanical properties of air operate in applying it to the mass of blood during its passage through the lungs. Suppose the thorax quite empty, and communicating with the external air by means of the trachea or windpipe, it would then resemble a pair of bellows. Raising the boards corresponds to the raising of the ribs; and we might imitate the action of the diaphragm by forcibly pulling outwards the folded leather which unites them. Thus their capacity is enlarged, and the air rushes in at the nozzle by its weight in the same manner as water would do. The thorax differs from bellows only in this respect, that it is filled by the lungs, which is a vast collection of little bladders, like the holes in a piece of fermented bread, all communicating with the trachea, and many of them with each other. When the chest is enlarged, the air rushes into them all in the same manner as into the single cavity of an empty thorax. It cannot be said with propriety that they are inflated; all that is done is the allowing the air to come in. At the same time, as their membranous covering must have some thickness, however small, and some elasticity, it is not unlikely that, when compressed by expiration, they tend a little to recover their former shape, and thus aid the voluntary action of the muscles. It is in this manner that a small bladder of caoutchouc swells again after compression, and fills itself with air or water. But this cannot happen except in the most minute vesicles; those of sensible bulk have not elasticity

Effects of the pressure of the air.

enough for this purpose. The lungs of birds, however, have some very large bladders, which have a very considerable elasticity, and recover their shape and size with great force after compression, and thus fill themselves with air. The respiration of these animals is considerably different from that of land animals, and their muscles act chiefly in expiration. This will be explained by and by as a curious variety in the pneumatic instrument.

Air taken in, not by our own action, but by external pressure.

This account of the manner in which the lungs are filled with air does not seem agreeable to the notions we entertain of it. We seem to suck in the air; but although it be true that we act, and exert force, in order to get air into our lungs, it is not by our action, but by external pressure, that it does come in. If we apply our mouth to the top of a bottle filled with water, we find that no draught, as we call it, of our chest will suck in any of the water, but if we suck in the very same manner at the end of a pipe immersed in water, it follows immediately. Our interest in the thing makes us connect in imagination our own action with the effect, without thinking on the many steps which may intervene in the train of natural operations; and we consider the action as the immediate cause of the reception of the air into the lungs. It is as if we opened the door, and took in by the hand a person who was really pushed in by the crowd without. If an incision be made into the side of the thorax, so that the air can get in by that way, when the animal acts in the usual manner, the air will really come in by this hole, and fill the space between the lungs and the thorax; but no air is sucked into the lungs by this process, and the animal is as completely suffocated as if the windpipe were shut up. And, on the other hand, if a hole be made into the lungs without communicating with the thorax, the animal will breathe through this hole, though the windpipe be stopped. This is successfully performed in cases of patients whose trachea is shut up by accident or by inflammation; only it is necessary that this perforation be made into a part of the lungs where it may meet with some of the great pulmonary passages; for if made into some remote part of a lobe, the air cannot find its way into the rest of the lungs through such narrow passages, obstructed too by blood, &c.

Nature of expiration.

We have now explained, on pneumatical principles, the process of inspiration. The expiration is chiefly performed by the natural tone of the parts. In the act of inspiration the ribs were raised and drawn outwards in opposition to the elasticity of the solids themselves; for although the ribs are articulated at their extremities, the articulations are by no means such as to give a free and easy motion like the joints of the limbs. This is particularly the case in the articulations with the sternum, which are by no means fitted for motion. It would seem that the motion really produced here is chiefly by the yielding of the cartilaginous parts and the bending of the rib; when therefore the muscles which produced this effect are allowed to relax, the ribs again collapse. Perhaps this is assisted a little by the action of the long muscles which come down across the ribs without being inserted into them. These may draw them together a little, as we compress a loose bundle by a string. In like manner, when the diaphragm was drawn down, it compressed the abdomen in opposition to the elasticity of all the viscera contained in it, and to the elasticity and tone of integuments and muscles which surround it. When therefore the diaphragm is relaxed, these parts push it up again into its natural situation, and in doing this expel the air from the lungs.

It requires no effort.

If this be a just account of the matter, expiration should be performed without any effort. This accordingly is the case. We feel that, after having made an ordinary easy inspiration, it requires the continuance of the effort to keep the thorax in this enlarged state, and that all that is necessary for expiration is to cease to act. No person feels any difficulty in emptying the lungs; but weak people often feel a difficulty of inspiration, and compare it to the feeling of a weight on their breast; and expiration is the last motion of the thorax in a dying person. But nature has also given us a mechanism by which we can expire, namely, the abdominal muscles; and when we have finished an ordinary and easy expiration, we can still expel a considerable bulk of air—nearly half the contents of the lungs—by contracting the abdominal muscles. These, by compressing the body, force up its moveable contents against the diaphragm, and cause it to rise further into the thorax, acting in the same manner as when we expel the fæces *per anum*. When a person breathes out as much air as he can in this manner, he may observe that his ribs do not collapse during the whole operation.

Effects of the pressure of the air

A certain quantity of air necessary to keep the lungs of a natural size.

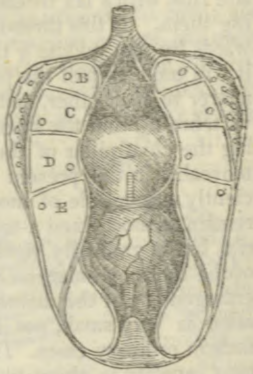
There seems then to be a certain natural unconstrained state of the vesicles of the lungs, and a certain quantity of air necessary for keeping them of this size. It is probable that this state of the lungs gives the freest motion to the blood. Were they more compressed, the blood-vessels would be compressed by the adjoining vesicles; were they more lax, the vessels would be more crooked, and by this means obstructed. The frequent inspirations gradually change this air by mixing fresh air with it, and at every expiration carrying off some of it. In catarrhs and inflammations, especially when attended with suppuration, the small passages into the remote vessels are obstructed, and thus the renewal of air in them will be prevented. The painful feeling which this occasions, causes us to expel the air with violence, shutting the windpipe, till we have exerted strongly with the abdominal muscles, and made a strong compression on the lower part of the thorax. We then open the passage suddenly, and expel the air and obstructing matter by violent coughing.

Process of breathing in birds.

We have said, that birds exhibit a curious variety in the process of breathing. The muscles of their wings being so very great, required a very extensive insertion, and this is one use of the great breast bone. Another use of it is, to form a firm partition to hinder the action of these muscles from compressing the thorax in the act of flying; therefore the form of their chest does not admit of alternate enlargement and contraction to that degree as in land animals. Moreover, the muscles of their abdomen are also very small; and it would seem that they are not sufficient for producing the compression on the bowels which is necessary for carrying on the process of concoction and digestion. Instead of aiding the lungs, they receive help from them.

In the ostrich, the lungs consist of a fleshy part A, A, (fig. 88) composed of vesicles like those of land animals, and, like theirs, serving to expose the blood to the action of the air. Besides these, they have on each side, four large bags, B, C, D, E, each of which has an orifice G, communicating with the trachea; but the second, C, has an orifice, H, by which it communicates with another bag F, situated below the rest in the abdomen. Now, when the lungs are compressed by the action of the diaphragm, the air in C is partly expelled by the trachea through the orifice G, and partly driven through the orifice H into the bag F, which is then allowed to receive it; because the same action which compresses the lungs enlarges the abdomen. When the thorax is enlarged, the bag C is partly supplied with fresh air through the trachea, and partly from the bag F. As the lungs of other animals resemble a common bellows, the

Fig. 88.



lungs of birds resemble the smith's bellows with a partition; and anatomists have discovered passages from this part of the lungs into their hollow bones and quills. We do not know all the uses of this contrivance; and only can observe, that this alternate action must assist the muscles of the abdomen in promoting the motion of the food along the alimentary canal, &c. We can distinctly observe in birds that their belly dilates when the chest collapses, and *vice versa*, contrary to what we see in the land animals. Another use of this double passage may be to produce a circulation of air in the lungs, by which a compensation is made for the smaller surface of action on the blood; for the number of small vesicles, of equal capacity with these large bags, give a much more extensive surface.

If we try to raise mercury in a pipe by the action of the chest alone, we cannot raise it above two or three inches; and the attempt is both painful and hazardous. It is painful chiefly in the breast, and it provokes coughing. Probably the fluids ooze through the pores of the vesicles by the pressure of the surrounding parts. On the other hand, we can by expiration support mercury about five or six inches high; but this also is very painful, and apt to produce extravasation of blood. This seems to be done entirely by the abdominal muscles.

The operation of sucking.

The operation properly termed *sucking*, is totally different from breathing, and resembles exceedingly the action of a common pump. Suppose a pipe held in the mouth, and its lower end immersed in water. We fill the mouth with the tongue, bringing it forward, and applying it closely to the teeth and to the palate; we then draw it back, or bend it downwards from the palate behind, thus leaving a void. The pressure of the air on the cheeks immediately depresses them, and applies them close to the gums and teeth; and its pressure on the water in the vessel causes it to rise through the pipe into the empty part of the mouth, which it quickly fills. We then push forward the tip of the tongue, below the water, to the teeth, and apply it to them all round, the water being above the tongue, which is kept much depressed. We then apply the tongue to the palate, beginning at the tip, and gradually going backward in this application. By this means the water is gradually forced backward by an operation similar to that of the gullet in swallowing. This is done by contracting the gullet above, and relaxing it below, just as we would empty a gut of its contents, by drawing our closed hand along it. By this operation the mouth is again completely occupied by the tongue, and we are ready for repeating the operation. Thus the mouth and tongue resemble the barrel and piston of a pump; and the application of the tip of the tongue to the teeth, performs the office of the valve at the bottom of the barrel, preventing the return of the water into the pipe. Although usual, it is not absolutely necessary, to withdraw the tip of the tongue, making a void before the tongue. Sucking may be performed by merely separating the tongue gradually from the palate, beginning at the root. If we withdraw the tip of the tongue a very minute quantity, the water flows back above the tongue.

The action of the tongue in this operation is very powerful; some persons can raise mercury 25 inches; but this strong exertion is very fatiguing, and the soft parts are prodigiously swelled by it. It causes the blood to ooze plentifully through the pores of the tongue, fauces, and palate, in the same manner as if a cupping-glass and syringe were applied to them; and, when the inside of the mouth is excoriated or tender, as is frequent with infants, even a very moderate exertion of this kind is accompanied with extravasation of blood. When children suck the nurse's breast, the milk follows their exertion by the pressure of the air on the breast; and a weak child, or one that withholds its exertions on account of pain from the above mentioned cause, may be assisted by a gentle pressure of the hand on the breast. The infant pupil of nature, without any knowledge of pneumatics, frequently helps itself by pressing its face to the yielding breast.

In the whole of this operation the breathing is performed through the nostrils; and it is a prodigious distress to an infant when this passage is obstructed by mucus. We beg to be forgiven for observing by the way, that this obstruction may be almost certainly removed for a little while, by rubbing the child's nose with any liquid of quick evaporation, or even with water.

Of drinking.

The operation in drinking is not very different from that in sucking. We have indeed little occasion here to suck, but we must do it a little. Dogs, and some other animals, cannot drink, but only lap the water into their mouths with their tongues, and then swallow it. The gallinaceous birds seem to drink very imperfectly. They seem merely to dip their head into the water, up to the eyes, till their mouth is filled with water, and then holding up the head, it gets into the gullet by its weight, and is then swallowed. The elephant drinks in a very complicated manner. He dips his trunk into the water, and fills it by making a void in his mouth. This he does in the contrary way to man. After having depressed his tongue, he begins the application of it to the palate at the root, and by extending the application forward, he expels the air by the mouth which came into it from the trunk. The process here is not very unlike that of the condensing syringe without a piston valve, in which the external air, corresponding to the air in the trunk, enters by the hole in the side, and is expelled through the hole in the end of the barrel; by this operation the trunk is filled with water; then he lifts his trunk out of the water, and bringing it to his mouth, pours the contents into it, and swallows it. On considering this operation, it appears that, by the same process by which the air of the trunk is taken into the mouth, the water could also be taken in, to be afterwards swallowed; but we do not find, upon inquiry, that this is done by the elephant; we have always observed him to drink in the manner now described. In either way it is a double operation, and cannot be carried on any way but by alternately sucking and swallowing, and while one operation is going on, the other is interrupted; whereas man can do both at the same time. Nature seems to delight in exhibiting to rational observers her inexhaustible variety of resource; for many insects which drink with a trunk, drink without interruption; yet we do not call in question the truth of the aphorism, *Natura maxime simplex et semper sibi consona*, nor doubt but that, if the *whole* of her purpose were seen, we should find that her process is the simplest possible; for Nature, or Nature's God, is wise above our wisest thoughts, and simplicity is certainly the choice of wisdom; but, alas! it is generally but a small and the most obvious part of her purpose that we can observe or appreciate. We seldom see this simplicity of nature stated to us, except by some system-maker, who has found a principle which somehow tallies with a considerable variety of phenomena, and then cries out, *Frustra sit per plura quod fieri potest per pauciora.*

Mode of keeping up a continued blast with a blow-pipe.

There is an operation similar to that of the elephant, which many find a great difficulty in acquiring; namely, keeping up a continued blast with a blow-pipe. We would desire our chemical reader to attend minutely to the gradual action of his tongue in sucking, and he will find it such as we have described. Let him attend particularly to the way in which the tip of the tongue performs the office of a valve, preventing the turn of the water into the pipe; and the same position of the tongue would hinder air from coming into the mouth. Next let him observe, that in swallowing what water he has now got lodged above his tongue, he continues the tip of the tongue applied to the teeth; now let him shut his mouth, keeping his lips firm together, the tip of the tongue at the

Effects of the pressure of the air.

teeth, and the whole tongue forcibly kept at a distance from the palate; bring up the tongue to the palate, and allow the tip to separate a little from the teeth, this will expel the air into the space between the fauces and cheeks, and will blow up the cheeks a little; then, acting with the tip of the tongue as a valve, hinder this air from getting back, and depressing the tongue again, more air from the nostrils will get into the mouth, which may be expelled into the space without the teeth as before, and the cheeks will be more inflated. Continue this operation, and the lips will no longer be able to retain it, and it will ooze through as long as the operation is continued. When this has become familiar and easy, take the blow-pipe, and there will be no difficulty in maintaining a blast as uniform as a smith's bellows, breathing all the while through the nostrils. The only difficulty is the holding the pipe. This fatigues the lips; but it may be removed by giving the pipe a convenient shape, a pretty flat oval, and wrapping it round with leather or thread.

Nature of the land and sea-breeze in warm countries.

Another phenomenon depending on the principles already established, is the land and sea-breeze in the warm countries. We have seen that air expands exceedingly by heat; therefore heated air, being lighter than an equal bulk of cold air, must rise in it. If we lay a hot stone in the sunshine in a room, we shall observe the shadow of the stone surrounded with a fluttering shadow of different degrees of brightness, and that this flutter rises rapidly in a column above the stone. If we hold an extinguished candle near the stone, we shall see the smoke move towards the stone, and then ascend from it. Now, suppose an island receiving the first rays of the sun in a perfectly calm morning; the ground will soon be warmed, and will warm the contiguous air. If the island be mountainous, this effect will be more remarkable; because the inclined sides of the hills will receive the light more directly. The midland air will therefore be most warmed. The heated air will rise, and that in the middle will rise fastest; and thus a current of air upwards will begin, which must be supplied by air coming in from all sides, to be heated and to rise in its turn; so that the morning sea-breeze is produced, and continues all day. This current will frequently be reversed during the night, by the air cooling and gliding down the sides of the hills, and we shall have the land-breeze.

Circulation of air in mines.

It is owing to the same cause that we have a circulation of air in mines which have the mouths of their shafts of unequal heights. The temperature under ground is pretty constant through the whole year, while that of the atmosphere is extremely variable. Now, suppose a mine having a long horizontal drift, communicating between two pits or shafts, and that one of these shafts terminates in a valley, while the other opens on the brow of a hill perhaps 100 feet higher. Let us further suppose it summer, and the air heated to 65°, while the temperature of the earth is but 45°; this last will be also the temperature of the air in the shafts and the drift. Now, since air expands nearly 24 parts in 10,000 by one degree of heat, we shall have an odds of pressure at the bottom of the two shafts equal to nearly the 20th part of the weight of a column of air 100 feet high (100 feet being supposed the difference of the heights of the shafts.) This will be about six ounces on every square foot of the section of the shaft. If this pressure could be continued, it would produce a prodigious current of air down the long shafts, along the drift, and up the short shaft. The weight of air acting through 100 feet would communicate to it the velocity of 80 feet per second: divide this by $\sqrt{20}$, that is, by 4·5, and we shall have 18 feet per second for the velocity: this is the velocity of what is called a brisk gale. This pressure would be continued, if the warm air which enters the long shaft were cooled and condensed as fast as it comes in; but this is not the case. It is however cooled and condensed, and a current is produced sufficient to make an abundant circulation of air along the whole passage; and care is taken to dispose the shafts and conduct the passages in such a manner that no part of the mine is out of the circle. When any new lateral drift is made, the renewal of air at its extremity becomes more imperfect as it advances: and when it is carried a certain length, the air stagnates and becomes suffocating, till either a communication can be made with the rest of the mine, or a shaft be made at the end of this drift.

Effects of the pressure of the air.

As this current depends entirely on the difference of temperature between the air below and that above, it must cease when this difference ceases. Accordingly, in the spring and autumn, the miners complain much of stagnation; but in summer they never want a current from the deep pits to the shallow, nor in the winter a current from the shallow pits to the deep ones. It frequently happens also, that in mineral countries the chemical changes which are going on in different parts of the earth occasion differences of temperature sufficient to produce a sensible current.

The nature of what is called the draught in chimneys.

And this naturally leads us to consider a very important effect of the expansion and consequent ascent of air by heat, namely, the drawing, as it is called, of chimneys. The air which has contributed to the burning of fuel must be intensely heated, and will rise in the atmosphere. This will also be the case with much of the surrounding air which has come very near the fire, although not in contact with it. If this heated air be made to rise in a pipe, it will be kept together, and therefore will not soon cool and collapse: thus we shall obtain a long column of light air, which will rise with a force so much the greater as the column is longer or more heated. Therefore the taller we make the chimney, or the hotter we make the fire, the more rapid will be the current, or the draught or suction, as it is injudiciously called, will be so much the greater. The ascensional force is the difference between the weight of the column of heated air in the funnel and a column of the surrounding atmosphere of equal height. We increase the draught, therefore, by increasing the perpendicular height of the chimney. Its length in a horizontal direction gives no increase, but, on the contrary, diminishes the draught by cooling the air before it gets into the effective part of the funnel. We increase the draught also by obliging all the air which enters the chimney to come very near the fuel; therefore a low mantle-piece will produce this effect; also filling up all the spaces on each side of the grate. When much air gets in above the fire, by having a lofty mantle-piece, the general mass of air in the chimney cannot be much heated. Hence it must happen that the greatest draught will be produced by bringing down the mantle-piece to the very fuel; but this converts a fire-place into a furnace, and by thus sending the whole air through the fuel, causes it to burn with great rapidity, producing a prodigious heat; and this producing an increase of ascensional force, the current becomes furiously rapid, and the heat and consumption of fuel immense. If the fire-place be a cube of a foot and a half, and the front closed by a door, so that all the air must enter through the bottom of the grate, a chimney of fifteen or twenty feet high, and sufficiently wide to give passage to all the expanded air which can pass through the fire, will produce a current which will roar like thunder, and a heat sufficient to run the whole inside into a lump of glass.

All that is necessary, however, in a chamber fire-place, is a current sufficiently great for carrying up the smoke and vitiated air of the fuel. And as we want also the enlivening light and flutter of the fire, we give the chimney-piece both a much greater height and width than what is merely necessary for carrying up the smoke, only wishing to have the current sufficiently determinate and steady for counteracting any occasional tendency which it may sometimes have to come into the room. By allowing a greater quantity of air to get into the chimney, heated only to a mode-ffects of e pres- e of the air.

rate degree, we produce a more rapid renewal of the air of the room: did we oblige it to come so much nearer the fire as to produce the same renewal of the air in consequence of a more rapid current, we should produce an inconvenient heat. But in this country, where pit-coal is in general so very cheap, we carry this indulgence to an extreme; or rather we have not studied how to get all the desired advantages with economy. A much smaller renewal of air than we commonly produce is abundantly wholesome and pleasant, and we may have all the pleasure of the light and flame of the fuel at much less expense, by contracting greatly the passage into the vent. The best way of doing this is by contracting the brick-work on each side behind the mantle-piece, and reducing it to a narrow parallelogram, having the back of the vent for one of its long sides. Make an iron plate to fit this hole, of the same length, but broader, so that it may lie sloping, its lower edge being in contact with the foreside of the hole, and its upper edge leaning on the back of the vent. In this position it shuts the hole entirely. Now let the plate have a hinge along the front or lower edge, and fold up like the lid of a chest. We shall thus be able to enlarge the passage at pleasure. In a fire-place fit for a room of 24 feet by 18, if this plate be about 18 inches long from side to side, and folded back within an inch or an inch and a half of the wall, it will allow passage for as much air as will keep up a very cheerful fire; and by raising or lowering this register, the fire may be made to burn more or less rapidly. A free passage of half an inch will be sufficient in weather that is not immoderately cold. The principle on which this construction produces its effect is, that the air which is in the front of the fire, and much warmed by it, is not allowed to get into the chimney, where it would be immediately hurried up the vent, but rises up to the ceiling and is diffused over the whole room. This double motion of the air may be distinctly observed by opening a little of the door and holding a candle in the way. If the candle be held near the floor, the flame will be blown into the room; but if held near the top of the door, the flame will be blown outward.

escrip- n of a ve-grate chapelle.

But the most perfect method of warming an apartment in the temperate climates, where we can indulge in the cheerfulness and sweet air produced by an open fire, is what we call a stove-grate, and our neighbours on the Continent call a chapelle, from its resemblance to the chapels or oratories in the great churches.

In the great chimney-piece, which, in this case, may be made even larger than ordinary, is set a smaller one fitted up in the same style of ornament, but of a size no greater than is sufficient for holding the fuel. The sides and back of it are made of iron (cast iron is preferable to hammered iron, because it does not so readily calcine), and are kept at a small distance from the sides and back of the main chimney-piece, and are continued down to the hearth, so that the ash-pit is also separated. The pipe or chimney of the stove grate is carried up behind the ornaments of the mantle-piece till it rises above the mantle-piece of the main chimney-piece, and is fitted with a register or damper-plate turning round a traverse axis. The best form of this register is that which we have recommended for an ordinary fire-place, having its axis or joint close at the front; so that when it is open or turned up, the burnt air and smoke striking it obliquely, are directed with certainty into the vent, without any risk of reverberating and coming out into the room. All the rest of the vent is shut up by iron-plates or brick-work out of sight.

The effect of this construction is very obvious. The fuel, being in immediate contact with the back and sides of the grate, heats them to a great degree, and they heat the air contiguous to them. This heated air cannot get up the vent, because the passages above these spaces are shut up. It therefore comes out into the room; some of it goes into the real fire-place and is carried up the vent, and the rest rises to the ceiling and is diffused over the room.

Effects of the pressure of the air.

Effect of its construction.

It is surprising to a person who does not consider it with skill, how powerfully this grate warms a room. Less than one-fourth of the fuel consumed in an ordinary fire-place is sufficient; and this with the same cheerful blazing hearth and salutary renewal of air. It even requires attention to keep the room cool enough. The heat communicated to those parts in contact with the fuel is needlessly great; and it will be a considerable improvement to line this part with very thick plates of cast-iron, or with tiles made of fire-clay which will not crack with the heat. These, being very bad conductors, will make the heat, ultimately communicated to the air, very moderate. If, with all these precautions, the heat should be found too great, it may be brought under perfect management by opening passages into the vent from the lateral spaces. These may be valves or trap-doors moved by rods concealed behind the ornaments.

Thus we have a fire-place under the most complete regulation, where we can always have a cheerful fire without being for a quarter of an hour incommoded by the heat; and we can as quickly raise our fire, when too low, by hanging on a plate of iron on the front, which shall reach as low as the grate. This in five minutes will blow up the fire into a glow; and the plate may be sent out of the room, or set behind the stove-grate out of sight.

The propriety of inclosing the ash-pit is not so obvious; but if this be not done, the light ashes, not finding a ready passage up the chimney, will come out into the room along with the heated air.

Mode of warming apartments by stoves.

Under this head we shall next give a general account and description of the method of warming apartments by stoves. A stove in general is a fire-place shut up on all sides, having only a passage for admitting the air to support the fire, and a tube for carrying off the vitiated air and smoke; and the air of the room is warmed by coming into contact with the outside of the stove and flue. The general principle of construction, therefore, is very simple. The air must be made to come into as close contact as possible with the fire, or even to pass through it, and this in such quantities as just to consume a quantity of fuel sufficient for producing the heat required; and the stove must be so constructed, that both the burning fuel and the air which has been heated by it shall be applied to as extensive a surface as possible of furnace, all in contact with the air of the room; and the heated air within the stove must not be allowed to get into the funnel which is to carry it off till it is too much cooled to produce any considerable heat on the outside of the stove.

In this temperate climate no great ingenuity is necessary for warming an ordinary apartment; and stoves are made rather to please the eye as furniture than as economical substitutes for an open fire of equal calorific power. But our neighbours on the Continent, and especially towards the north, where the cold of winter is intense and fuel very dear, have bestowed much attention on their construction, and have combined ingenious economy with every elegance of form. Nothing can be handsomer than the stoves of Fayencerie that are to be seen in French Flanders, or the Russian stoves at St. Petersburg, finished in stucco. Our readers will not, therefore, be displeased with a description of them. In this place, however, we shall only consider a stove in general as a subject of pneumatical discussion, and refer our readers to the article Stove for stoves as articles of domestic accommodation.

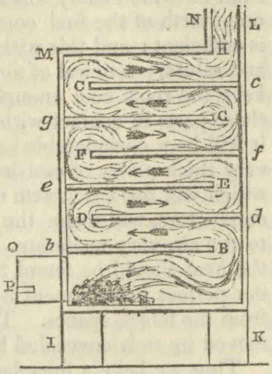
General form of a stove.

The general form, therefore, of a stove, and of which all others are only modifications adapted to circumstances of utility or taste, is as follows:—MIKL (fig. 79.) is a quadrangular box of any size in the directions MILK. The inside width from front to back is pretty constant, never less than 10 inches, and rarely extending to 20;

Effects of the pressure of the air.

the included space is divided by a great many partitions. The lowest chamber B is the receptacle for the fuel, which lies on the bottom of the stove without any grate; this fire-place has a door AO turning on hinges, and in this door is a very small wicket P: the roof of the fire-place extends to within a very few inches of the farther end, leaving a narrow passage B for the flame. The next partition *c* C is about eight inches higher, and reaches almost to the other end, leaving a narrow passage for the flame at C. The partitions are repeated above, at the distance of eight inches, leaving passages at the ends, alternately disposed as in the figure; the last of them H communicates with the room vent. This communication may be regulated by a plate of iron, which can be slid across it by means of a rod or handle which comes through the side. The more usual way of shutting up this passage is by a sort of pan or bowl of earthen ware, which is whelmed over it with its brim resting in sand contained in a groove formed all round the hole. This damper is introduced by a door in the front, which is then shut. The whole is set on low pillars, so that its bottom may be a few inches from the floor of the room. It is usually placed in a corner, and the apartments are so disposed that their chimneys can be joined in stacks as with us.

Fig. 79.



Some straw or wood shavings are first burnt on the hearth at its farther end. This warms the air in the stove, and creates a determined current. The fuel is then laid on the hearth close by the door, and pretty much piled up. It is now kindled; and the current being already directed to the vent, there is no danger of any smoke coming out into the room. Effectually to prevent this, the door is shut, and the wicket P opened. The air supplied by this, being directed to the middle or bottom of the fuel, quickly kindles it, and the operation goes on.

Aim and effects of this construction.

The aim of this construction is very obvious. The flame and heated air are retained as long as possible within the body of the stove by means of the long passages; and the narrowness of these passages obliges the flame to come in contact with every particle of soot, so as to consume it completely, and thus convert the whole combustible matter of the fuel into heat. For want of this, a very considerable portion of our fuel is wasted by our open fires, even under the very best management. The soot which sticks to our vents is very inflammable, and a pound weight of it will give as much if not more heat than a pound of coal. And what sticks to our vents is very inconsiderable in comparison with what escapes unconsumed at the chimney top. In fires of green wood, peat, and some kinds of pit-coal, nearly one-fifth of the fuel is lost in this way; but in these stoves there is hardly ever any mark of soot to be seen; and even this small quantity is produced only after lighting the fires. The volatile inflammable matters are expelled from parts much heated indeed, but not so hot as to burn; and some of it charred or half-burnt cannot be any further consumed, being enveloped in flame and air already vitiated and unfit for combustion. But when the stove is well heated, and the current brisk, no part of the soot escapes the action of the air.

The hot air retained in this manner in the body of the stove is applied to its sides in a very extended surface. To increase this still more, the stove is made narrower from front to back in its upper part; a certain breadth is necessary below, that there may be room for fuel. If this breadth were preserved all the way up, much heat would be lost, because the heat communicated to the partitions of the stove does no good. By diminishing their breadth, the proportion of useful surface is increased. The whole body of the stove may be considered as a long pipe folded up, and its effect would be the greatest possible if it really were so; that is, if each partition *c*C, *d*D, &c. were split into two, and a free passage allowed between them for the air of the room. Something like this will be observed afterwards in some German stoves.

Effects of the pressure of the air.

It is with the same view of making an extensive application of a hot surface to the air, that the stove is not built in the wall, not even in contact with it, nor with the floor; for by its detached situation, the air in contact with the back, and with the bottom, where it is hottest, is warmed, and contributes at least one-half of the whole effect; for the great heat of the bottom makes its effect on the air of the room at least equal to that of the two ends. Sometimes a stove makes part of the wall between two small rooms, and is found sufficient.

It must be remarked, on the whole, that the effect of a stove depends much on keeping in the room the air already heated by it. This is so remarkably the case, that a small open fire in the same room will be so far from increasing its heat, that it will greatly diminish it; it will even draw the warm air from a suite of adjoining apartments. This is distinctly observed in the houses of the English merchants in St. Petersburg; their habits of life in Britain make them uneasy without an open fire in their sitting rooms; and this obliges them to heat all their stoves twice a-day, and their houses are cooler than those of the Russians, who heat them only once. In many German houses, especially of the lower class, the fire-place of the stove does not open into the room, but into the yard or a lobby, where all the fires are lighted and tended; by this means is avoided the expense of warm air which must have been carried off by the stove; but it is evident, that this must be very unpleasant, and cannot be wholesome. We must breathe the same quantity of stagnant air loaded with all the vapours and exhalations which must be produced in every inhabited place. Going into one of these houses from the open air, is like putting one's head into a stew-pan or under a pie-crust, and quickly nauseates us who are accustomed to fresh air and cleanliness. In these countries it is a matter almost of necessity, to fumigate the rooms with frankincense and other gums burnt. The censer in ancient worship was in all probability an utensil introduced by necessity for sweetening or rendering tolerable the air of a crowded place; and it is a constant practice in the Russian houses for a servant to go round the room after dinner, waving a censer with some gums burning on bits of charcoal.

Of hot walls in gardening, &c.

The account now given of stoves for heating rooms, and of the circumstances which must be attended to in their construction, will equally apply to hot walls in gardening, whether within or without doors. The only new circumstance which this employment of a flue introduces, is the attention which must be paid to the equability of the heat, and the gradation which must be observed in different parts of the building. The heat in the flue gradually diminishes as it recedes from the fire-place, because it is continually giving out heat to the flue. It must therefore be so conducted through the building by frequent returns, that in every part there may be a mixture of warmer and cooler branches of the flue, and the final chimney should be close by the fire-place. It would, however, be improper to run the flue from the end of the floor up to the ceiling, where the second horizontal pipe would be placed, and then return it downward again and make the third horizontal flue adjoining to the first, &c. This would make the middle of the wall the coldest. If it is the flue of a greenhouse, this would be highly improper, because the upper part of the wall can be very little employed; and in this case it is bet-ffects of e pres- re of the air.

ter to allow the flue to proceed gradually up the wall in its different returns, by which the lowest part would be the warmest, and the heated air will ascend among the pots and plants; but in a hot wall, where the trees are to receive heat by contact, some approximation to the above method may be useful. In the hypocausta and fudaria of the Greeks and Romans, the flue was conducted chiefly under the floors.

alt-kilns pecies of ove.

Malt-kilns are a species of stove which merit our attention. Many attempts have been made to improve them on the principle of flue stoves; but they have been unsucessful, because heat is not what is chiefly wanted in malting; it is a copious current of very dry air to carry off the moisture.

f the cur- nt of air melting rnaces.

All that is to be attended to in the different kinds of melting furnaces is, that the current of air be sufficiently rapid, and that it be applied in as extensive a surface as possible to the substance to be melted. The more rapid the current it is the hotter, because it is consuming more fuel; and therefore its effect increases in a higher proportion than its rapidity. It is doubly effectual if twice as hot; and if it then be twice as rapid, there is twice the quantity of doubly hot air applied to the subject; it would therefore be four times more powerful. This is procured by raising the chimney of the furnace to a greater height. The close application of it to the subject can hardly be laid down in general terms, because it depends on the precise circumstances of each case.

rrent in erbera- y furna- e.

In reverberatory furnaces, such as refining furnaces for gold, silver, and copper, the flame is made to play over the surface of the melted metal. This is produced entirely by the form of the furnace, by making the arch of the furnace as low as the circumstances of the manipulation will allow. See Furnace. Experience has pointed out in general the chief circumstances of their construction, viz. that the fuel should be at one end on a grate, through which the air enters to maintain the fire; and that the metal should be placed on a level floor between the fuel and the tall chimney which produces the current. But there is no kind of furnace more variable in its effect, and almost every place has a small peculiarity of construction, on which its preeminence is rested. This has occasioned many whimsical varieties in their form. This uncertainty seems to depend much on a circumstance rather foreign to our present purpose; but as we do not observe it taken notice of by mineralogical writers, we beg leave to mention it here. It is not heat alone that is wanted in the refining of silver by lead, for instance. We must make a continual application to its surface of air, which has not contributed to the combustion of the fuel. Any quantity of the hottest air, already saturated with the fuel, may play on the surface of the metal for ever, and keep it in the state of most perfect fusion, but without refining it in the least. Now, in the ordinary construction of a furnace, this is much the case. If the whole air has come in by the grate, and passed through the middle of the fuel, it can hardly be otherwise than nearly saturated with it; and if air be also admitted by the door, which is generally done or something equivalent, the pure air lies above the vitiated air, and during the passage along the horizontal part of the furnace, and along the surface of the metal, it still keeps above it, at least there is nothing to promote their mixture. Thus the metal does not come into contact with air fit to act on the base metal and calcine it, and the operation of refining goes on slowly. Trifling circumstances in the form of the arch or canal may tend to promote the jumbling of the airs together, and thus render the operation more expeditious; and as these are but ill understood, or perhaps this circumstance not attended to, no wonder that we see these considered as so many nostrums of great importance. It were therefore worth while to try the effect of changes in the form of the roof directed to this very circumstance. Perhaps some little prominence down from the arch of the reverberatory would have this effect, by suddenly throwing the current into confusion. If the additional length of passage do not cool the air too much, we should think that if there were interposed between the fuel and the refining floor a passsage twisted like a cork-screw, making just half a turn, it would be most effectual; for we imagine, that the two airs, keeping each to their respective sides of the passage, would by this means be turned upside down, and that the pure stratum would now be in contact with the metal, and the vitiated air would be above it.

Effects of the pressure of the air.

Current in the glass-house furnaces.

The glass-house furnace exhibits the chief variety in the management of the current of heated air. In this it is necessary that the hole at which the workman dips his pipe into the pot shall be as hot as any part of the furnace. This could never be the case, if the furnace had a chimney situated in a part above the dipping-hole; for in this case cold air would immediately rush in at the hole, play over the surface of the pot, and go up the chimney. To prevent this the hole itself is made the chimney; but as this would be too short, and would produce very little current and very little heat, the whole surface is set under a tall dome. Thus the heated air from the real furnace is confined in this dome, and constitutes a high column of very light air, which will therefore rise with great force up the dome, and escape at the top. The dome is therefore the chimney, and will produce a draught or current proportioned to its height. Some are raised above a hundred feet. When all the doors of this house are shut, and thus no supply given except through the fire, the current and heat become prodigious. This, however, cannot be done, because the workmen are in this chimney, and must have respirable air. But notwithstanding this supply by the house-doors, the draught of the real furnace is vastly increased by the dome, and a heat produced sufficient for the work, and which could not have been produced without the dome.

Cotterel's improvement for melting iron from the ore.

This has been applied with great ingenuity and effect to a furnace for melting iron from the ore, and an iron finery, both without a blast. The common blast iron furnace is well known. It is a tall cone with the apex undermost. The ore and fluxes are thrown into this cone mixed intimately with the fuel till it is full, and the blast of most powerful bellows is directed into the bottom of this cone through a hole in the side. The air is thrown in with such force, that it makes its way through the mass of matter, kindles the fuel in its passage, and fluxes the materials, which then drop down into a receptacle below the blast-hole, and thus the passage for the air is kept unobstructed. It was thought impossible to produce or maintain this current without bellows; but Mr. Cotterel, an ingenious founder, tried the effect of a tall dome placed over the mouth of the furnace, and though it was not half the height of many glass-house domes it had the desired effect.

Currents of air applied to free mines, &c. of noxious air.

The last application which we shall make of the currents produced by heating the air is to the freeing mines, ships, prisons, &c. from the damp and noxious vapours which frequently infest them. As a drift or work is carried on in the mine, let a trunk of deal boards, about six or eight inches square, be laid along the bottom of the drift, communicating with a trunk carried up in the corner of one of the shafts. Let the top of this last trunk open into the ash-pit of a small furnace, having a tall chimney. Let fire be kindled in the furnace; and when it is well heated, shut the fire-place and ash-pit doors. There being no other supply for the current produced in the chimney of this furnace, the air will flow into it from the trunk, and will bring along with it all the offensive vapours. This is the most effectual method yet found out. In the same manner may trunks be conducted into the ash-pit of a furnace from the cells of a prison or the wards of an hospital.

In the account which we have been giving of the management of air in furnaces and common fires, we have frequently mentioned the immediate application of air to the burning fuel as necessary for its combustion. This is a general fact.

Air necessary for the combustion of fuel.

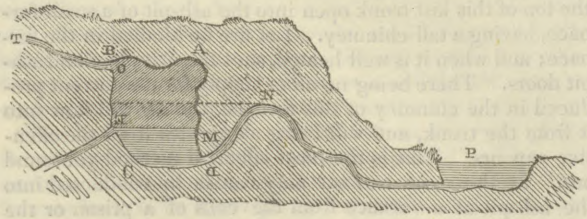
In order that any inflammable body may be readily inflamed, and its combustible matter consumed and ashes produced, it is not enough that the body be made hot. A piece of charcoal inclosed in a box of iron may be kept red hot for ever, without wasting its substance in the smallest degree. It is further necessary that it be in contact with a particular species of air, which constitutes about three-fourths of the air of the atmosphere, viz. the vital air or oxygen of Lavoisier. It was called empyreal air by Scheele, who first observed its indispensable use in maintaining fire; and it appears, that, in contributing to the combustion of an inflammable body, this air combines with some of its ingredients, and becomes fixed air, suffering the same change as by the breathing of animals. Combustion may therefore be considered as a solution of the inflammable body in air. This doctrine was first promulgated by the celebrated Dr. Hooke in his *Micrographia*, published in 1660, and afterwards improved in his *Treatise on Lamps*. It is now completely established, and considered as a new discovery. It is for this reason, that in fire-places of all kinds we have directed the construction, so as to produce a close application of the air to the fuel. It is quite needless at this day to enter into the discussions which formerly occupied philosophers about the manner in which the pressure and elasticity of the air promoted combustion. Many experiments were made in the seventeenth century by the first members of the Royal Society, to discover the office of air in combustion. It was thought that the flame was extinguished in rare air for want of a pressure to keep it together; but this did not explain its extinction when the air was not renewed. These experiments are still retained in courses of experimental philosophy, as they are judiciously styled; but they give little or no information, nor tend to the illustration of any pneumatical doctrine; they are therefore omitted in this place. In short, it is now fully established, that it is not a mechanical but a chemical phenomenon. We can only inform the chemist, that a candle will consume faster in the low countries than in the elevated regions of Quito and Gondar, because the air is nearly one half denser below, and will act proportionally faster in decomposing the candle.

Curious effect of the pressure of the air.

We shall conclude this part of our subject with the explanation of a curious phenomenon observed in many places. Certain springs or fountains are observed to have periods of repletion and scantiness, or seem to ebb and flow at regular intervals; and some of these periods are of a complicated nature. Thus a well will have several returns of high and low water, the difference of which gradually increases to a maximum, and then diminishes, just as we observe in the ocean. A very ingenious and probable explanation of this has been given in No. 424 of the *Philosophical Transactions*, by Mr. Atwell.

Let ABCD (fig. 90,) represent a cavern, into which water is brought by the subterraneous passage OT. Let it have an outlet MNP, of a crooked form, with its highest part N considerably raised above the bottom of the cavern, and thence sloping downwards into lower ground, and terminating in an open well at P. Let the dimensions of this canal be such that it will discharge much more water than is supplied by TO. All this is very natural, and may be very common. The effect of this arrangement will be a remitting spring at P; for when the cavern is filled higher than the point N, the canal MNP will act as a syphon; and, by the conditions assumed, it will discharge the water faster than TO supplies it; it will therefore run it dry, and then the spring at P will cease to furnish water. After some time the cavern will again be filled up to the height N, and the flow at P will recommence.

Fig. 90.



If, besides this supply, the well P also receive water from a constant force, we shall have a reciprocating spring. The situation and dimensions of this syphon canal, and the supply of the feeder, may be such, that the efflux at P will be constant. If the supply increase in a certain degree, a reciprocation will be produced at P with very short intervals; if the supply diminishes considerably, we shall have another kind of reciprocation with great intervals and great differences of water.

If the cavern have another simple outlet R, new varieties will be produced in the spring P, and R will afford a copious spring. Let the mouth of R, by which the water enters into it from the cavern, be lower than N, and let the supply of the feeding spring be no greater than R can discharge, we shall have a constant spring from R, and P will give no water. But suppose that the main feeder increases in winter or in rainy seasons, but not so much as will supply both P and R, the cavern will fill till the water gets over N, and R will be running all the while; but soon after P has begun to flow, and the water in the cavern sinks below R, the stream from R will stop. The cavern will be emptied by the syphon canal MNP, and then P will stop. The cavern will then begin to fill, and when near full R will give a little water, and soon after P will run and R stop as before, &c. Desaguliers shows (vol. ii. p. 177, &c.) in what manner a prodigious variety of periodical ebbs and flows may be produced by underground canals, which are extremely simple and probable.

Account of some pneumatic engines.

We shall conclude this article with the descriptions of some pneumatical machines or engines which have not been particularly noticed under their names in the former volumes of this work.

Bellows are of most extensive and important use; and it will be of service to describe such as are of uncommon construction and power, sufficient for the great operations in metallurgy.

It is not the impulsive force of the blast that is wanted in most cases, but merely the copious supply of air, to produce the rapid combustion of inflammable matter; and the service would be better performed in general if this could be done with moderate velocities, and an extended surface. What are called air-furnaces, where a considerable surface of inflammable matter is acted on at once by the current which the mere heat of the expended air has produced, are found more operative in proportion to the air expended than blast furnaces animated by bellows; and we doubt not but that the method proposed by Mr. Cotterel, which we have already mentioned, of increasing this current in a melting furnace by means of a dome, will in time supersede the blast furnaces. There is indeed a great impulsive force required in some cases; as for blowing off the scoriæ from the surface of silver or copper in refining furnaces, or for keeping a clear passage for the air in the great iron furnace.

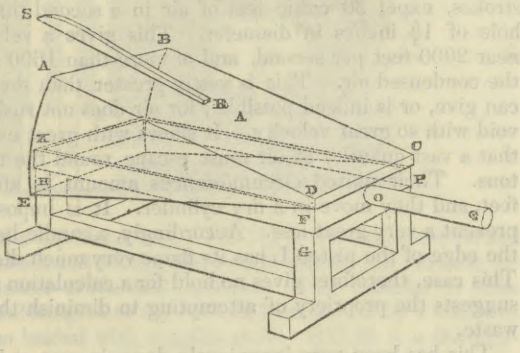
In general, however, we cannot procure this abundant supply of air any other way than by giving it a great velocity by means of a great pressure, so that the general construction of bellows is pretty much the same in all kinds.

eumatic
ngines.

The air is admitted into a very large cavity, and then expelled from it through a small hole.

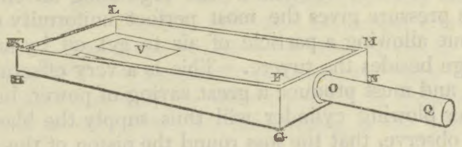
The furnaces at the mines having been greatly enlarged, it was necessary to enlarge the bellows also; and the leathern bellows becoming exceedingly expensive, wooden ones were substituted in Germany about the beginning of the seventeenth century, and from them became general throughout Europe. They consist of a wooden box ABCPFE, fig. 91,

Fig. 91.



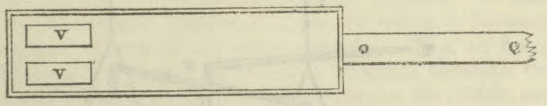
which has its top and two sides flat or straight, and the end BAE formed into an arched or cylindrical surface, of which the line FP at the other end is the axis. This box is open below, and receives within it the shallow box KHGNML, fig. 92, which exactly fills it. The line FP

Fig. 92.



of the one coincides with FP of the other, and along this line is a set of hinges on which the upper box turns as it rises and sinks. The lower box is made fast to a frame fixed in the ground. A pipe OQ proceeds from the end of it, and terminates at the furnace, where it ends in a small pipe called the *tewer* or *tuyere*. This lower box is open above, and has in its bottom two large valves V, V, fig. 93, opening

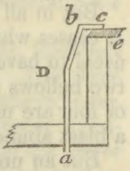
Fig. 93.



inwards. The conducting pipe is sometimes furnished with a valve opening outwards, to prevent burning coals from being sucked into the bellows when the upper box is drawn up. The joint along PF is made tight by thin leather nailed along it. The sides and ends of the fixed box are made to fit the sides and curved end of the upper box, so that this last can be raised and lowered round the point FP without sensible friction, and yet without suffering much air to escape; but as this would not be sufficiently air-tight by reason of the shrinking and warping of the wood, a farther contrivance is adopted. A slender lath of wood, divided into several joints, and covered on the outer edge with very soft leather, is laid along the upper edges of the sides and ends of the lower box. This lath is so broad, that when its inner edge is even with the inside of the box, its outer edge projects about an inch. It is kept in this position by a number of steel wires, which are driven into the bottom of the box, and stand up touching the sides, as represented in fig. 94, where *a b c* are the wires, and *e* the lath, projecting over the outside of the box. By this contrivance the laths are pressed close to the sides and curved end of the moveable box, and the spring wires yield to all their inequalities. A bar of wood RS, fig. 91, is fixed to the upper board, by which it is either raised by machinery, to sink again by its own weight, having an additional load laid on it, or it is forced downward by a crank or wiper of the machinery, and afterwards raised.

Pneumatic
engines.

Fig. 94.



The operation here is precisely similar to that of blowing with a chamber-bellows. When the board is lifted up, the air enters by the valves V, V, fig. 93, and is expelled at the pipe OQ by depressing the boards. There is therefore no occasion to insist on this point.

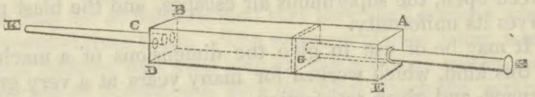
These bellows are made of a very great size, AD being 16 feet, AB five feet, and the circular end AE also five feet. The rise, however, is but about 3 or $3\frac{1}{2}$ feet. They expel at each stroke about 90 cubic feet of air, and they make about 8 strokes per minute.

Such are the bellows in general use on the continent. We have adopted a different form in this kingdom, which seems much preferable. We use an iron or wooden cylinder, with a piston sliding along it. This may be made with much greater accuracy than the wooden boxes, at less expense, if of wood, because it may be of cooper's work, held together by hoops; but the great advantage of this form is its being more easily made air-tight. The piston is surrounded with a broad strap of thick and soft leather, and it has around its edge a deep groove, in which is lodged a quantity of wool. This is called the packing or stuffing, and keeps the leather very closely applied to the inner surface of the cylinder. Iron cylinders may be very neatly bored and smoothed, so that the piston, even when very tight, will slide along it very smoothly. To promote this, a quantity of black lead is ground very fine with water, and a little of this is smeared on the inside of the cylinder from time to time.

The cylinder has a large valve, or sometimes two, in the bottom, by which the atmospheric air enters when the piston is drawn up. When the piston is thrust down, this air is expelled along a pipe of great diameter, which terminates in the furnace with a small orifice.

This is the simplest form of bellows which can be conceived. It differs in nothing but size from the bellows used by the rudest nations. The Chinese smiths have a bellows very similar, being a square pipe of wood ABCDE, fig. 95,

Fig. 95.



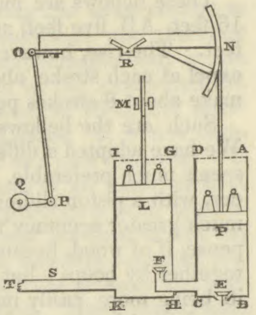
with a square board G which exactly fits it, moved by the handle FG. At the farther end is the blast pipe HK, and on each side of it a valve in the end of the square pipe, opening inwards. The piston is sufficiently tight for their purposes without any leathering.

The piston of this cylinder bellows is moved by machinery. In some blast engines the piston is simply raised by the machine, and then let go, and it descends by its own weight, and compresses the air below it to such a degree, that the velocity of efflux becomes constant, and the piston descends uniformly; for this purpose it must be loaded with a proper weight. This produces a very uniform blast, except at the very beginning, whilst the piston falls suddenly and compresses the air; but in most engines the piston rod is forced down the cylinder with a determined motion, by means of a beam, crank, or other contrivance. This gives a more unequal blast, because the motion of the piston is necessarily slow in the beginning and end of the stroke, and quicker in the middle.

But in all it is plain that the blast must be desultory. It ceases while the piston is rising; for this reason it is usual to have two cylinders, as it was formerly usual to have two bellows which worked alternately. Sometimes three or four are used, as at the Carron iron-works. This makes a blast abundantly uniform.

But an uniform blast may be made with a single cylinder, by making it deliver its air into another cylinder, which has a piston exactly fitted to its bore, and loaded with a sufficient weight. The blowing cylinder ABCD, fig. 96, has its piston P worked by a rod NP, connected by double chains with the arched head of the working beam NO, moving round a gudgeon at R. The other end O of this beam is connected by the rod OP, with the crank PQ of a wheel machine; or it may be connected with a piston of a steam-engine, &c. &c. The blowing cylinder has a valve or valves E in its bottom, opening inwards. There proceeds from it a large pipe CF, which enters the regulating cylinder GHKI, and has a valve at top to prevent the air from getting back into the blowing cylinder. It is evident that the air forced into this cylinder must raise its piston L, and that it must afterwards descend, while the other piston is rising. It must descend uniformly, and make a perfectly equable blast.

Fig. 96.



Observe, that if the piston L be at the bottom when the machine begins to work, it will be at the bottom at the end of every stroke if the *tuyere* T emits as much air as the cylinder ABCD furnishes; nay, it will lie a while at the bottom, for, while it was rising, air was issuing through T. This would make an interrupted blast. To prevent this, the orifice T must be lessened; but then there will be a surplus of air at the end of each stroke, and the piston L will rise continually, and at last get to the top, and allow air to escape. It is just possible to adjust circumstances, so that neither shall happen. This is done easier by putting a stop in the way of the piston, and putting a valve on the piston, or on the conducting pipe KST, loaded with a weight a little superior to the intended elasticity of the air in the cylinder. Therefore, when the piston is prevented by the stop from rising, the snifting valve, as it is called, is forced open, the superfluous air escapes, and the blast preserves its uniformity.

It may be of use to give the dimensions of a machine of this kind, which worked for many years at a very great furnace, and given satisfaction.

The diameter of the blowing cylinder is 5 feet, and the length of the stroke is 6. Its piston is loaded with 3½ tons. It is worked by a steam-engine whose clyinder is 3 feet 4 inches wide, with a six-feet stroke. The regulating cylinder is 8 feet wide, and its piston is loaded with 8½ tons, making about 2.63 pounds on the square inch; and it is very nearly in equilibrio with the load on the piston of the blowing cylinder. The conducting pipe KST is 12 inches in diameter, and the orifice of the tuyere was ⅝ths of an inch when the engine was erected, but it has gradually enlarged by reason of the intense heat to which it is exposed. The snifting valve is loaded with 3 pounds on the square inch.

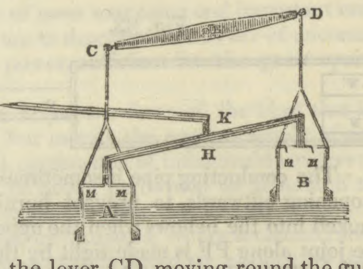
When the engine worked briskly, it made 18 strokes per minute, and there was always much air discharged by the snifting valve. When the engine made 15 strokes per minute, the snifting valve opened but seldom, so that things were nearly adjusted to this supply. Each stroke of the blowing cylinder sent in 118 cubic feet of common air. The ordinary pressure of the air being supposed 14¾ pounds on an inch, the density of the air in the regulating cylinder must be $\frac{14.75+2.63}{14.75}$, =1.1783, the natural density being 1.

This machine gives an opportunity of comparing the expense of air with the theory. It must, at the rate of 15 strokes, expel 30 cubic feet of air in a second through a hole of 1⅝ inches in diameter. This gives a velocity of near 2000 feet per second, and of more than 1600 feet for the condensed air. This is vastly greater than the theory can give, or is indeed possible; for air does not rush into a void with so great velocity. It shows with great evidence, that a vast quantity of air must escape round the two pistons. Their united circumferences amount to above 40 feet, and they move in a dry cylinder. It is impossible to prevent a very great loss. Accordingly, a candle held near the edge of the piston L has its flame very much disturbed. This case, therefore, gives no hold for a calculation; and it suggests the propriety of attempting to diminish this great waste.

This has been very ingeniously done, in part at least, at some other furnaces. At a certain foundery, near Glasgow, the blowing cylinder, also worked by a steam-engine, delivers its air into a chest without a bottom, which is immersed in a large cistern of water, and supported at a small height from the bottom of the cistern, and has a pipe from its top leading to the tuyere. The water stands about five feet above the lower brim of the regulating air-chest, and by its pressure gives the most perfect uniformity of blast, without allowing a particle of air to get off by any other passage besides the tuyere. This is a very effectual regulator, and must produce a great saving of power, because a smaller blowing cylinder will thus supply the blast. We must observe, that the loss round the piston of the blowing cylinder remains undiminished.

A blowing machine was erected many years ago at Chastillon in France on a principle considerably different, and which must be perfectly air-tight throughout. Two cylinders A, B, (fig. 97) loaded with great weights, were suspended at the ends of the lever CD, moving round the gudgeon E. From the top F, G of each there was a large flexible pipe which united in H, from whence a pipe KT led to the tuyere T. There were valves at F and G opening outwards, or into the flexible pipes; and other valves L, M, adjoining to them in the top of each cylinder, opening inwards, but kept shut by a slight spring. Motion was given to the lever by a machine. The operation of this blowing machine is evident. When the cylinder A was pulled down, or allowed to descend, the water, entering at its bottom, compressed the air, and forced it along the passage FHKT. In the mean time, the cylinder B was rising, and the air entered by the valve M. We see that the blast will be very unequal, increasing as the cylinder is immersed deeper. It is needless to describe this machine more particularly, because we shall give an account of one which we think per-

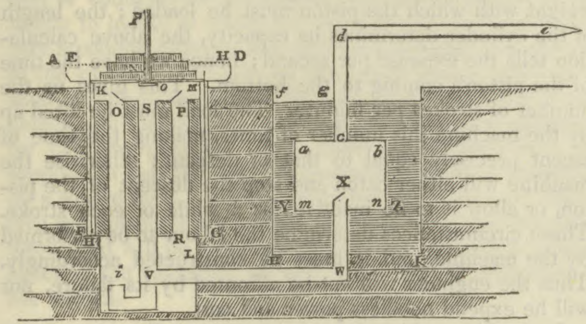
Fig. 97.



fect in its kind, and which leaves hardly any thing to be desired in a machine of this sort.

ABCD (fig. 98) is an iron cylinder, truly bored within, and evasated a-top like a cup. EFGH is another, truly turned both without and within, and a small matter less than the inner diameter of the first cylinder. This cylinder is close above and hangs from the end of a level moved by a machine. It is also loaded with weights at N. KILM is a third cylinder, whose outside diameter is somewhat less than the inside diameter of the second. This inner cylinder is fixed to the same bottom with the outer cylinder. The middle cylinder is loose, and can move up and down between the outer and inner cylinders without rubbing on either of them. The inner cylinder is perforated from top to bottom by three pipes OQ, SV, PR. The pipes OQ, PR have valves at their upper ends O, P, and communicate with the external air below. The pipe SV has a horizontal part VW, which again turns upwards, and has a valve at top X. This upright part WX is in the middle of a cistern of water *fhkg*. Into this cistern is fixed an air-chest *a* YZ *b*, open below, and having at top a pipe *cde* terminating in the tuyere at the furnace.

Fig. 98.



When the machine is at rest, the valves X, O, P, are shut by their own weights, and the air-chest is full of water. When things are in this state, the middle cylinder EFGH is drawn up by the machinery till its lower brims F and G are equal with the top RM of the inner cylinder. Now pour in water or oil between the outer and middle cylinders; and it will run down and fill the space between the outer and inner cylinders. Let it come to the top of the inner cylinder.

Now, let the loaded middle cylinder descend. It cannot do this without compressing the air which is between its top and the top of the inner cylinder. This air being compressed, will cause the water to descend between the inner and middle cylinders, and rise between the middle and outer cylinders, spreading into the cup; and as the middle cylinder advances downwards, the water will descend farther within it, and rise farther without it. When it has got so far down, and the air has been so much compressed, that the difference between the surface of the water on the inside and outside of this cylinder is greater than the depth of water between X and the surface of the water *fg*, air will go out by the pipe SVW, and will lodge in the air-chest, and will remain there if *c* be shut, which we shall suppose for the present. Pushing down the middle cylinder till the partition touch the top of the inner cylinder, all the air which was formerly between them will be forced into the air-chest, and will drive out water from it. Draw up the middle cylinder, and the external air will open the valves O, P, and again fill the space between the middle and inner cylinders; for the valve X will shut, and prevent the regress of the condensed air. By pushing down the middle cylinder a second time, more air will be forced into the air-chest, and it will at last escape by getting out between its brims Y, Z, and the bottom of the cistern; or if we open the passage *c*, it will pass along the conduit *c d e* to the tuyere, and form a blast.

The operation of this machine is similar to Mr. Haskins's quicksilver pump, described by Desaguliers.[1] The force which condenses the air is the load on the middle cylinder. The use of the water between the inner and outer cylinders, is to prevent this air from escaping; and the inner cylinder thus performs the office of a piston, having no friction. It is necessary that the length of the outer and middle cylinders be greater than the depth of the regulator-cistern, that there may be a sufficient height for the water to rise between the middle and outer cylinders, to balance the compressed air, and oblige it to go into the air-chest. A large blast-furnace will require the regulator-cistern five feet deep, and the cylinders about six or seven feet long.

It is in fact a pump without friction, and is perfectly air-tight. The quickness of its operation depends on the small space between the middle cylinder and the two others; and this is the only use of these two. Without these it would be similar to the engine at Chastillon, and operate more unequally and slowly. Its only imperfection is, that if the cylinder begin its motion of ascent or descent rapidly, as it will do when worked by a steam engine, there will be some danger of water dashing over the top of the inner cylinder, and getting into the pipe SV; but should this happen, an issue can easily be contrived for it at V, covered with a loaded valve *v*. This will never happen if the cylinder is moved by a crank. One blowing cylinder only is represented here, but two may be used.

We do not hesitate in recommending this form of bellows as the most perfect of any, and fit for all uses where standing bellows are required. They will be cheaper than any other sort for common purposes. For a common smith's forge they may be made with square wooden boxes instead of cylinders. They are also easily repaired. They are perfectly tight; and they may be made with a blast almost perfectly uniform, by making the cistern in which the air-chest stands, of considerable dimensions. When this is the case, the height of water, which regulates the blast, will vary very little.

This may suffice for an account of blast machines. The leading parts of their construction have been described as far only as was necessary for understanding their operation, and enabling an engineer to erect them in the most commodious manner. Views of complete machines might have amused, but they would not have added to our reader's information.

But the account is imperfect unless we show how their parts may be so proportioned that they shall perform what is expected from them. The engineer should know what size of bellows, and what load on the board or piston, and what size of tuyere, will give the blast which the service requires, and what force must be employed to give them the necessary degree of motion. We shall accomplish these purposes by considering the efflux of the compressed air through the tuyere. The propositions formerly delivered will enable us to ascertain this.

That we may proportion everything to the power employed, we must recollect, that if the piston of a cylinder employed for expelling air, be pressed down with any force p, it must be considered as superadded to the atmospheric pressure P on the same piston, in order that we may compare the velocity v of efflux with the known velocity V with which air rushes into a void. By what has been formerly delivered, it appears that this velocity $v = \mathrm{V} \times \sqrt{\frac{p}{\mathrm{P} \times p}}$,

---

[1] *Experimental Philosophy*, vol. ii. p. 491; and *Philosophical Transactions*, 1728, vol. xxxii. p. 5.

Pneumatic engines.

where P is the pressure of the atmosphere on the piston, and p the additional load laid on it. This velocity is expressed in feet per second; and, when multiplied by the area of the orifice (also expressed in square feet) it will give us the cubical feet of condensed air expelled in a second; but the bellows are always to be filled again with common air, and therefore we want to know the quantity of common air which will be expelled; for it is this which determines the number of strokes which must be made in a minute, in order that the proper supply may be obtained. Therefore recollect that the quantity expelled from a given orifice with a given velocity, is in the proportion of the density; and that when D is the density of common air produced by the pressure P, the density d produced by the pressure $P+p$, is $D \times \frac{P+p}{P}$; or if D be made 1, we have $d = \frac{P+p}{P}$.

Therefore, calling the area of the orifice expressed in square feet O, and the quantity of common air, or the cubic feet expelled in a second Q, we have $Q = V \times O \times \sqrt{\frac{p}{P+p}} \times \frac{P+q}{P}$

It will be sufficiently exact for all practical purposes, to suppose P to be 15 pounds on every square inch of the piston; and p is then conveniently expressed by the pounds of additional load on every square inch. We may also take $V=1332$ feet.

As the orifice through which the air is expelled is generally very small, never exceeding three inches in diameter, it will be more convenient to express it in square inches; which being the $\frac{1}{144}$th of a square foot, we shall have the cubic feet of common air expelled in a second, or $Q = \frac{1332}{144} O \sqrt{\frac{p}{P+p}} \times \frac{P+p}{P}, = O \times 9{\cdot}25 \times \sqrt{\frac{p}{P+p}} \times \frac{P+p}{P}$; and this seems to be as simple an expression as we can obtain.

This will perhaps be illustrated by taking an example in numbers. Let the area of the piston be four square feet, and the area of the round hole through which the air is expelled, be two inches, its diameter being 1.6, and let the load on the piston be 1728 pounds; this is three pounds on every square inch. We have $P=15$, $p=3$, $P+p=18$, and $O=2$; therefore we will have $Q = 2 \times 9.25 \times \sqrt{\frac{3}{18}} \times \frac{18}{15}, = 9.053$ cubic feet of common air expelled in a second. This will however be diminished at least one-third by the contraction of the jet; and therefore the supply will not exceed six cubic feet per second. Supposing therefore that this blowing machine is a cylinder or prism of this dimension in its section, the piston so loaded would, after having compressed the air, descend about 15 inches in a second. It would first sink one-fifth of the whole length of the cylinder pretty suddenly, till it had reduced the air to the density $\frac{18}{15}$, and would then descend uniformly at the above rate, expelling six cubic feet of common air in a second.

The computation is made much in the same way for bellows of the common form, with this additional circumstance, that as the loaded board moves round a hinge at one end, the pressure of the load must be calculated accordingly. The computation, however, becomes a little intricate, when the form of the loaded board is not rectangular. It is almost useless when the bellows have flexible sides, either like smith's bellows or like organ bellows, because the change of figure during their motion makes continual variation on the compressing powers. It is therefore chiefly with respect to the great wooden bellows, of which the upper board slides down between the sides, that the above calculation is of service.

The propriety, however, of this piece of information is evident: we do not know precisely the quantity of air necessary for animating a furnace; but this calculation tells us what force must be employed for expelling the air that may be thought necessary. If we have fixed on the strength of the blast, and the diameter of the cylinder, we learn the weight with which the piston must be loaded; the length of the cylinder determines its capacity, the above calculation tells the expense per second; hence we have the time of the piston's coming to the bottom. This gives us the number of strokes per minute. The load must be lifted up by the machine this number of times, making the time of ascent precisely equal to that of descent; otherwise the machine will either catch and stop the descent of the piston, or allow it to lie inactive for a while of each stroke. These circumstances determine the labour to be performed by the machine, and it must be constructed accordingly. Thus the engineer will not be affronted by its failure, nor will he expend needless power and cost.

In machines which force the piston or bellows board with a certain determined motion, different from what arises from their own weight, the computation is extremely intricate. When a piston moves by a crank, its motion at the beginning and end of each stroke is slow, and the compression and efflux is continually changing. We can however approximate to a statement of the force required.

Every time the piston is drawn up, a certain space of the cylinder is filled again with air of the common density; and this is expelled during the descent of the piston. A certain number of cubic feet of common air is therefore expelled with a velocity which perhaps continually varies; but there is a medium velocity with which it might have been uniformly expelled, and a pressure corresponding to this velocity. To find this, divide the area of the piston by the area of the blast-hole (or rather by this area multiplied by 0·613, in order to take in the effect of the contracted jet), and multiply the length of the stroke performed in a second by the quotient arising from this division; the product is the medium velocity of the air (of the natural density). Then find by calculation the height through which a heavy body must fall in order to acquire this velocity; this is the height of a column of homogeneous air which would expel it with this velocity. The weight of this column is the least force that can be exerted by the engine: but this force is too small to overcome the resistance in the middle of the stroke, and it is too great even for the end of the stroke, and much too great for the beginning of it. But if the machine is turned by a very heavy water-wheel, this will act as a regulator, accumulating in itself the superfluous force during the too favourable positions of the crank, and exerting it by its *vis insita* during the time of greatest effort. A force not greatly exceeding the weight of this column of air will therefore suffice. On the other hand, if the strength of the blast be determined, which is the general state of the problem, this determines the degree of condensation of the air, and the load on the square inch of the piston, or the mean force which the machine must exert on it. A table, which will be given presently, determines the cubic feet of common air expelled in a second, corresponding to this load. This combined with the proposed dimensions of the cylinder, will give the descent of the piston or the length of the stroke.

These general observations apply to all forms of bellows; and without a knowledge of them no person can erect a machine for working them without total uncertainty or servile imitation. In order, therefore, that they may be useful to such as are not accustomed to the management of even these simple formulæ, we insert the following short table of the velocity and quantity of air discharged from a cylinder whose piston is loaded with the pounds contained in the first column on every square inch. The second column contains the velocity with which the *condensed air* rushes out through any *small* hole; and the third column is the cubic feet discharged from a hole whose area is a square inch; column fourth contains the mean velocity of air of the common density; and column fifth is the cubic feet of common air discharged; the sixth column is the height in inches at which the force of the blast would support a column of water if a pipe were inserted into the side of the cylinder. This is an extremely proper addition to such machines, showing at all times the power of the machines, and teaching us what intensity of blast is employed for different purposes. The table is computed from the supposition that the ordinary pressure of the air is 15 pounds on a square inch. This is somewhat too great, and therefore the velocities are a little too small; but the quantities discharged will be found about one-third too great, without affecting the velocities, on account of the convergency of the stream.

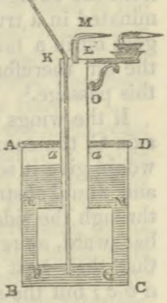
I	II	III	IV	V	VI
½	239	1·66	249	1·72	14
1	333	2·32	355	2·47	27
1½	404	2·79	437	3·05	40
2	457	3·17	518	3·60	54
2½	500	3·48	584	4·2	68
3	544	3·76	653	4·53	82
3½	582	4·03	715	4·98	95
4	611	4·24	774	5·38	109
4½	642	4·46	822	5·75	122
5	666	4·67	888	6·17	136
5½	693	4·84	950	6·49	150
6	711	5·06	997	6·92	163

This table extends far beyond the limits of ordinary use, very few blast-furnaces having a force exceeding 60 inches of water.

We shall conclude this account of blowing machines with a description of a small one for a blow-pipe. ABCD, (fig. 99) is a vessel containing water, about two feet deep. EFGH is the air-box of the blower open below, and having a pipe ILK rising up from it to a convenient height; an arm ON which grasps this pipe carries the lamp N: the blow-pipe LM comes from the top of the upright pipe. PKQ is the feeding-pipe reaching near to the bottom of the vessel.

Water being poured into the vessel below, and its cover being put on, which fits the upright pipe, and touches two studs *a*, *a*, projecting from it, blow in a quantity of air by the feeding pipe PQ; this expels the water from the air-box, and occasions a pressure which produces the blast through the blow-pipe M.

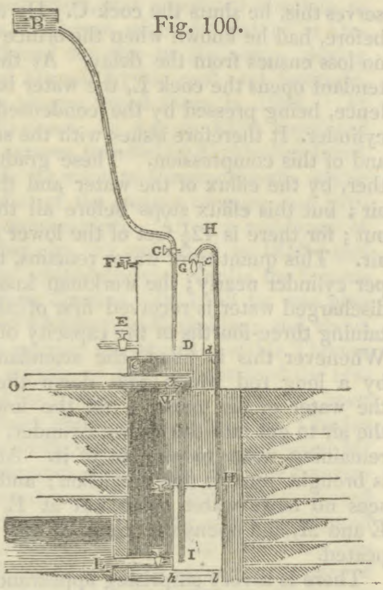
Fig. 99.



In a preceding part of this article, we mentioned an application which has been made of Hero's fountain, at Chemnitz in Hungary, for raising water from the bottom of a mine. We shall now give an account of this very ingenious contrivance.

In fig. 100, B represents the source of water elevated above the mouth of the pit 136 feet. From this there is led a pipe B*b*CD four inches diameter. This pipe enters the top of a copper cylinder *b c d e*, 8½ feet high, five feet diameter, and two inches thick, and it reaches to within four inches of the bottom; it has a cock at C. This cylinder has a cock at F, and a very large one at E. From the top *b c* proceeds a pipe GHH′ two inches in diameter, which goes down the pit 96 feet, and is inserted into the top of another brass cylinder *f g h i*, which is 6½ feet high, four feet diameter, and two inches thick, containing 83 cubic feet, which is very nearly one-half of the capacity of the other, viz. of 170 cubic feet. There is another pipe NI of four inches diameter, which rises from within four inches of the bottom of this lower cylinder, is soldered into its top, and rises to the trough NO, which carries off the water from the mouth of the pit. This lower cylinder communicates at the bottom with the water L which collects in the drains of the mine. A large cock K serves to admit or exclude this water; another cock M, at the top of this cylinder, communicates with the external air.

Fig. 100.



Now, suppose the cock C shut, and all the rest open; the upper cylinder will contain air, and the lower cylinder will be filled with water, because it is sunk so deep that its top is below the usual surface of the mine-waters. Now, shut the cocks F, E, M, K, and open the cock C. The water of the source B must run in by the orifice D, and rise in the upper cylinder, compressing the air above it and along the pipe GHH′, and thus acting on the surface of the water in the lower cylinder. It will therefore cause it to rise gradually in the pipe IN, where it will always be of such a height that its weight balances the elasticity of the compressed air. Suppose no issue given to the air from the upper cylinder, it would be compressed into one-fifth of its bulk by the column of 136 feet high; for a column of 34 feet nearly balances the ordinary elasticity of the air. Therefore, when there is an issue given to it through the pipe GHH′, it will drive the compressed air along this pipe, and it will expel water from the lower cylinder. When the upper cylinder is full of water, there will be 34 cubic feet of water expelled from the lower cylinder. If the pipe IN had been more than 136 feet long, the water would have risen 136 feet, being then in equilibrio with the water in the feeding pipe B*b*CD, by the intervention of the elastic air; but no more water would have been expelled from the lower cylinder than what fills this pipe. But the pipe being only 96 feet high, the water will be thrown out at N with a very great velocity. If it were not for the great obstructions which water and air must meet with in their passage along pipes, it would issue at N with a velocity of more than 50 feet per second. It issues much more slowly, and at last the upper cylinder is full of water, and the water would enter the pipe GH and enter the lower cylinder, and without displacing the air in it, would rise through the discharging pipe IN, and run off to waste. To prevent this there hangs in the pipe HG a cork ball or double cone, by a brass wire which is guided by holes in two cross pieces in the pipe HG. When the upper cylinder is filled with water, this cork plugs up the orifice G, and no water is wasted; the influx at D now stops. But the lower cylinder contains compressed air, which would balance water in a discharging pipe 136 feet high, whereas IN is only 96. Therefore the water will continue to flow at N till the air has so far expanded as to balance only 96 feet of water, that is, till it occupies one-fourth of its ordinary bulk, that is, one-fourth of the capacity of the upper cylinder, or 42½ cubic feet. Therefore 42½ cubic feet will be expelled, and the efflux at N will cease; and the lower cylinder is about one-half full of water. When the attending workman observes this, he shuts the cock C. He might have done this before, had he known when the orifice G was stopped; but no loss ensues from the delay. At the same time the attendant opens the cock E, the water issues with great violence, being pressed by the condensed air from the lower cylinder. It therefore issues with the sum of its own weight and of this compression. These gradually decrease together, by the efflux of the water and the expansion of the air; but this efflux stops before all the water has flowed out; for there is 42½ feet of the lower cylinder occupied by air. This quantity of water remains, therefore, in the upper cylinder nearly; the workman knows this, because the discharged water is received first of all into a vessel containing three-fourths of the capacity of the upper cylinder. Whenever this is filled, the attendant opens the cock E by a long rod which goes down the shaft; this allows the water of the mine to fill the lower cylinder, allows the air to get into the upper cylinder, and this allows the remaining water to run out of it. And thus every thing is brought into its first condition; and when the attendant sees no more water come out at E, he shuts the cock E and M, and opens the cock C, and the operation is repeated.

There is a very surprising appearance in the working of this engine. When the efflux at N has stopped, if the cock F be opened, the water and air rush out together with prodigious violence, and the drops of water are changed into hail or lumps of ice. It is a sight usually shown to strangers, who are desired to hold their hats to receive the blast of air: the ice comes out with such violence as frequently to pierce the hat like a pistol bullet. This rapid congelation is a remarkable instance of the general fact, that air by suddenly expanding, generates cold, its capacity for heat being increased. Thus the peasant cools his broth by blowing over the spoon, even from warm lungs; a stream of air from a pipe is always cooling.

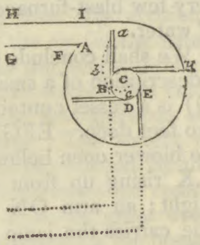
The above account of the procedure in working this engine shows that the efflux both at N and E becomes very slow near the end. It is found convenient therefore not to wait for the complete discharges, but to turn the cocks when about 30 cubic feet of water have been discharged at N: more work is done in this way. A gentleman of great accuracy and knowledge of these subjects took the trouble, at our desire, of noticing particularly the performance of the machine. He observed that each stroke, as it may be called, took up about three minutes and one-eighth; and that 32 cubic feet of water were discharged at N, and 66 were expended at E. The expense, therefore, is 66 feet of water falling 136 feet, and the performance is 32 raised 96, and they are in the proportion of 66×136 to 32×96, or of 1 to 0·3422, or nearly as 3 to 1. This is superior to the performance of the most perfect undershot mill, even when all friction and irregular obstructions are neglected, and is not much inferior to any overshot pump-mill that has yet been erected. When we reflect on the great obstructions which water meets with in its passage through long pipes, we may be assured that, by doubling the size of the feeder and discharger, the performance of the machine will be greatly improved; we do not hesitate to say, that it would be increased one-third: it is true that it will expend more water, but this will not be nearly in the same proportion, for most of the deficiency of the machine arises from the needless velocity of the first efflux at N. The discharging pipe ought to be 110 feet high, and not give sensibly less water. Then it must be considered how inferior in original expense this simple machine must be to a mill of any kind which would raise 10 cubic feet 96 feet high in a minute, and how small the repairs on it need be, when compared with a mill. And, lastly, let it be noticed, that such a machine can be used where no mill whatever can be put in motion. A small stream of water, which would not move any kind of wheel, will here raise one-third of its own quantity to the same height, working as fast as it is supplied.

For all these reasons, we think that the Hungarian machine eminently deserves the attention of mathematicians and engineers, to bring it to its utmost perfection, and into general use. There are situations where this kind of machine may be very useful. Thus, where the tide rises 17 feet, it may be used for compressing air to seven-eighths of its bulk; and a pipe leading from a very large vessel inverted in it, may be used for raising the water from a vessel of one-eighth of its capacity 17 feet high; or if this vessel has only one-tenth of the capacity of the large one set in the tide-way, two pipes may be led from it, one into the small vessel and the other into an equal vessel 16 feet higher, which receives the water from the first. Thus one-sixteenth of the water may be raised 34 feet, and a smaller quantity to a still greater height, and this with a kind of power that can hardly be applied in any other way. Machines of this kind are described by Schottus, Sturmius, Leupold, and other old writers; and they should not be forgotten, because opportunities may offer of making them highly useful. A gentleman's house in the country may thus be supplied with water by a machine that will cost little, and hardly go out of repair.

The last pneumatical engine which we shall speak of at present is the common fanners, used for winnowing grain, and for drawing air out of a room; and we have but few observations to make on them.

The wings of the fanners are enclosed in a cylinder or drum, whose circular sides have a large opening BDE, (fig. 101), round the centre, to admit the air. By turning the wings rapidly round, the air is hurried round along with them, and thus acquires a centrifugal tendency, by which it presses strongly on the outer rim of the drum: this is gradually detached from the circle as at KI, and terminated in a trunk IHGF, which goes off in a tangential direction; the air therefore is driven along this passage.[1]

Fig. 101.



If the wings were disposed in planes passing through the axis C, the compression of the air by the anterior surface would give it some tendency to escape in every direction, and would obstruct in some degree the arrival of more air through the side holes. They are therefore reclined a little backward, as represented in the figure. It may be shown that their best form would be that of a hyperbolic spiral *a b c*; but the straight form approaches sufficiently near to the most perfect shape.

Much labour is lost, however, in carrying the air round those parts of the drum where it cannot escape. The fanners would either draw or discharge almost twice as much air if an opening were made all round one side. This could be gradually contracted, where required for winnowing, by a surrounding cone, and thus directed against the falling grain; as has been verified by actual trial. When used for drawing air out of a room for ventilation, it would be much better to remove the outer side of the drum entirely, and let the air fly freely off on all sides; but the flat sides are necessary, in order to prevent the air from arriving at the fanners any other way but through the central holes, to which trunks should be fitted leading to the apartment which is to be ventilated. (B. B. B.)

---

[1] A machine precisely similar is now extensively used instead of bellows by engineers, smiths, &c.

PO, Padus, Eridanus, one of the great rivers of Europe, which traverses the north of Italy from west to east. It has its source in Monte Viso, one of the Cottian Alps, flows north-east to Turin, passes that capital, holds an easterly course throughout the whole length of Lombardy, separating Austrian Italy from Parma, Modena, and the Ecclesiastical States, and discharges itself by a number of mouths into the Adriatic, about thirty miles to the south of Venice. In its course, which, including its windings, is upwards of 500 miles, it receives a great number of rivers, flowing in full current from the Alps on the north, and in less copious but equally rapid streams from the Apennines on the south. Of these tributary waters the principal are, the Dora Riparia, the Dora Baltea, the Stura, the Orco, the Sesia, the Tanaro, the Ticino, the Adda, the Olona, the Oglio, the Mincio, the Crostolo, and the Panaro. The Po, rising in a very mountainous country, soon becomes a large river, and is sufficiently deep to float boats and barges at thirty miles from its source; but its current is often so rapid that the navigation is at all seasons difficult, and not unfrequently hazardous. Hence, though it passes in its progress more than fifty towns, little advantage comparatively is derived from it for the conveyance of merchandise. Its volume of water is subject to sudden increase from the melting of the snows, and from heavy falls of rain, the rivers that flow into it being almost all mountain streams; and in the flat country, in the lower part of its course, this would have been attended with very destructive effects, if great dykes had not been constructed to confine it within its channel. The gravel rolled down from the mountains has progressively raised the bed of the river, and the protecting mounds have also been correspondingly elevated; so that the Po, in the lower part of its course, presents the singular spectacle of a vast body of water, the level of which is higher than that of the adjoining country. Its borders, interspersed with trees and villages, display great luxuriance of vegetation, and are extremely pleasant, though by no means picturesque. This river, like the Rhine, is crossed by flying bridges. A post is fixed in the middle of the stream, and a rope conveyed from it to the passage raft, by means of a number of small boats which form the connecting links; and these boats being pressed on by the current, guide the raft to the opposite side, with no other assistance than that of an oar. The raft usually consists of two barges boarded over, and encompassed with a rail. Lastly, the basin of the Po has been the theatre of some of the most remarkable military operations of modern times; more particularly of the campaigns of Eugene, Napoleon, and Suwarof, who, each in his turn, decided, for the time, the fate of Italy.

POBASSOO'S Island, a small island on the north coast of New Holland; forming, with Cotton's Island, a secure shelter for shipping, which Captain Flinders called Malay Road. Long. of this road 136. 27. E. Lat. 11. 53. S.

POCKLINGTON, a market-town of Yorkshire, in the east riding, and the wapentake of Harthill, 193 miles from London. It is situated on a small stream that falls into the river Derwent, and has a market, which is held on Saturday. The population amounted in 1801 to 1502, in 1811 to 1539, in 1821 to 1962, and in 1831 to 2048; but the whole parish, which comprehends three other townships, had at the last census 2265 inhabitants.

POCOCK'S Island is situated in the Eastern Seas. Long. 118. 12. E. Lat. 6. 2. S.

POCOCK'S Point, on the east coast of New Zealand, was formerly the north-west point of the Bay of Islands. It is four miles west of Cape Brett.

POCOCKE, Dr Edward, a learned English divine, and the first oriental scholar of his time, was the eldest son of Edward Pococke; and born in November 1604, at Oxford, where he was also educated. In 1628 he was admitted probationer-fellow of his college, and about the same time he had prepared an edition of the second Epistle of St Peter, the second and third of St John, and the Epistle of St Jude, in Syriac and Greek, with a Latin translation and notes. In 1629 he was ordained priest, and appointed chaplain to the English merchants at Aleppo, where he arrived in October 1630, and continued for five or six years, during which he distinguished himself by his zeal and fortitude, particularly whilst the plague raged there in 1634. At length returning to England, he was in 1636 appointed reader of the Arabic Lectures, founded by Archbishop Laud. Three years afterwards he went to Constantinople, where he prosecuted his studies of the eastern tongues, and procured many valuable manuscripts. After a residence of nearly four years in that city, he embarked in 1640; and taking Paris in his way, visited Gabriel Sionita the famous Maronite, and also Hugo Grotius. In 1643 he was presented to the rectory of Childrey, in Berkshire; and about three years afterwards married the daughter of Mr Thomas Burdett. About the middle of 1647 he obtained the restitution of the salary of his Arabic Lecture, which had been detained from him about three years. In 1648, Charles I., being then prisoner in the Isle of Wight, nominated Mr Pococke to the professorship of Hebrew, and the canonry of Christ-Church annexed to it; but in 1650 he was ejected from his canonry for refusing to take the engagement, and soon afterwards a vote passed for depriving him of his Hebrew and Arabic professorships. But several governors of houses, and others, having presented a petition in his favour, he was suffered to enjoy both these places. He had some years before published his *Specimen Historiæ Arabum*, a very learned work, and now appeared his *Porta Mosis;* and soon afterwards the English Polyglot edition of the Bible, to which he had largely contributed, and also Eutychius's Annals, with a Latin version, gave evidence of his industry and learning. At the Restoration he was reinstated in the canonry of Christ-Church, and also received the degree of doctor of divinity. He then published his Arabic version of Grotius's Treatise of the Truth of the Christian Religion; and an Arabic poem entitled *Lamiato l'Ajam* or *Carmen Abu-Ismaelis Tograi*, with a Latin translation and notes. Soon afterwards he published Gregory Abulfaragius's *Historia Dynastiarum;* but this work did not meet with much encouragement from the public, a circumstance which his biographer accounts for in a manner not very creditable to the reign of Charles II. as compared with the protectorate, when solid learning was appreciated and rewarded. The fact seems to be, that the love of Arabic learning was now growing cold; and Pococke himself, in his correspondence with Mr Thomas Greaves, appears to be not only sensible that such was the case, but very much hurt by the decline of sound literary taste. The same circumstance also may in some measure account for this distinguished scholar not having obtained higher preferment at the period of the Restoration, when such numbers of vacant dignities were conferred on far inferior men. Perhaps he was almost the only instance of a clergyman, then at the highest pitch of eminence for learning, and every other merit proper to his profession, who lived throughout the reign of Charles II. without the least regard from the court, except the favour sometimes done him of being called upon to translate Arabic letters from the princes of the Levant, or the credentials of ambassadors coming from thence; a service for which we do not find that he obtained any recompense, besides fair words and hollow compliments. But his modesty equalled his merit; and after presenting Abulfaragius to the king, he ceased to obtrude his claims on the attention of royalty. In 1674 he published an Arabic version of the principal parts of the Liturgy of the Church of England; and a few years afterwards appeared his Commentary on the Prophecies of Micah, Malachi, Hosea, and Joel. This truly great man died in 1691, after having been for many years confessedly the first orientalist in Europe; and he was no less worthy of admiration for his uncommon modesty and humility, and all the virtues which can adorn a Christian. His theological works were republished at London in 1740, in two volumes folio.

Pococke, *Richard*, distantly related to the preceding, was the son of Mr Richard Pococke, head master of the free-school at Southampton, where he was born in the year 1704. He received his school-learning under his father, and his academical education at Corpus Christi College, Oxford, where he took his various degrees. He commenced his travels in the East in 1737, and returned in 1742. In 1743, he published his Observations on Egypt, under the general title of a Description of the East and some other Countries. In 1744, he was made precentor of Waterford; and in 1745, he printed the second volume of his Travels, under the title of Observations on Palestine or the Holy Land, Syria, Mesopotamia, Cyprus, and Candia, which he dedicated to the Earl of Chesterfield, then lord-lieutenant of Ireland, whom he attended in the capacity of domestic chaplain. In 1756, Dr Pococke was promoted to the bishopric of Ossory, vacant by the death of Dr Edward Maurice; in July 1765, he was translated to the see of Meath, which had been originally intended for the Bishop of Elphin, who, however, declined taking out his patent; and he died suddenly in September following, having been carried off by apoplexy, whilst engaged in visiting his diocese. As a traveller Dr Pococke was equally distinguished for research, learning, and accuracy, to which ample justice has indeed been done by Jablonski, in the preface to part third of his *Pantheon Ægyptiorum*. He penetrated no farther up the Nile than the island of Philæ, called by the Arabs the Temple Island; whereas Norden, in 1737, proceeded as far as Derré, between the first and second cataract. The two travellers are supposed to have met on the Nile, in the neighbourhood of Esneh, in January 1738; but, according to another account, they passed in the night without recognition.

Bishop Pococke visited other parts besides the East, and described some remarkable objects both in Scotland and Ireland. According to Cumberland, he was a man of mild but peculiar manners, and of primitive simplicity. "Having given the world," says this writer, "a full detail of his researches in Egypt, he seemed to hold himself excused from saying anything more about them, and observed, in general, an obdurate taciturnity. In his carriage and deportment he appeared to have contracted something of the Arab character; yet there was no austerity in his silence, and though his air was solemn, his temper was serene." Cumberland adds: "When we were on our road to Ireland, I saw from the windows of the inn at Daventry a cavalcade of horsemen approaching on a gentle trot, headed by an elderly chief in clerical attire, who was followed by five servants at distances geometrically measured and most precisely maintained, and who, upon entering the inn, proved to be this distinguished prelate conducting his horde with the phlegmatic patience of a scheik." Cumberland's delineation, however, must be received with some caution, particularly in the latter part, which bears evident marks of exaggeration.

PODALIRIUS, son of Æsculapius and Epione, was one of the pupils of the centaur Chiron, under whom he made himself such a master of medicine, that during the Trojan war the Greeks invited him to their camp to check a pestilence which had baffled the skill of all their physicians. On his return Podalirius was shipwrecked upon the coast of Caria, where he cured of epilepsy a daughter of the king of the place. He fixed his habitation there; and built two towns, one of which he called after his wife *Syrna*. On his death, the Carians built him a temple, and paid him divine honours.

PODGORODKOI, a fortress of Asiatic Russia, in the government of Oufa, on the Oural. It is ninety-two miles east of Orenburg.

PODEM, a village of Asiatic Turkey, in Trebisond, thirty miles east of Trebisond.

PODEMNO, a village of Tobolsk, in Asiatic Russia, forty-four miles east of Kemskoi.

PODENDA, a village of Asia Minor, at the junction of the Sihoun with the Adana, thirty-three miles north of Adana.

PODOL, a town of Russia, in the province of Moskau, the capital of a circle of the same name, which extends over 590 square miles, and contains 58,800 inhabitants. The town is situated on the river Pochra, 508 miles from St Petersburg, and contains only 1100 inhabitants, who carry on some silk manufactures. Long. 37. 25. E. Lat. 55. 25. N.

PODOLIA, a province or government of the Russian empire, formerly a part of Poland, acquired by Russia at the first dismemberment of that unfortunate kingdom. It extends in north latitude from 47. 23. to 49. 44., and in east longitude from 26. 16. to 30. 41.; and it is bounded on the north by Volhynia, on the north-east by Kiew, on the east and south-east by Cherson, on the south by Bessarabia, and on the west by the Austrian kingdom of Gallicia. It is 20,796 miles in extent, is divided into twelve circles, and contains 121 towns, 2429 villages, with 1,450,000 inhabitants, a great part of whom are Poles, but many are Russians; and the Jews are numerous. The majority are of the Greek church, but the nobility and higher classes commonly adhere to the Roman Catholic worship.

The province is situated on the northern slope of the Carpathian Mountains, several of the spurs of which project into it, but none are more than 500 feet in height. It is a well-watered district, part of the streams of which fall into the Dniester, and part into the Bug; the former of which is at all seasons navigable, but the latter only one portion of the year. The climate is pure and healthy, but it is not productive of wine, which is supposed to arise from the want of calcareous earth. Mulberry-trees have been lately planted, and seem hitherto to have succeeded. The soil is generally fertile, yielding always a great surplus of grain, especially of wheat, some of which finds a vent at Odessa, and some at Dantzig. It is peculiarly adapted to pasture, and feeds numerous horses, and a breed of cows, which are highly prized, and supply a large extent of country with young cattle and fat oxen, even as far as a part of Germany. The sheep are abundant, but their wool is coarse; and few merinos have hitherto been introduced to improve the breed. Flax and hemp are raised to an extent equal to the consumption of the inhabitants. The manufactures are chiefly for domestic use; but some potash, pitch, and tar, are made for exportation. Though possessing a fruitful soil, and means of communication with both the north and the south, there is little trade, except occasionally that of corn.

PODSTEPNOI, a fortress of Asiatic Russia, in the government of Kolivan, on the Irtisch, two hundred miles south-east of Omsk.

PODSPUSKNOI, a fortress of Asiatic Russia, in the government of Kolivan, 220 miles south-west of Kolivan.

PŒCILE was a famous portico at Athens, which received its name from the variety (ποικιλος) of paintings which it contained. Zeno kept his school there; and there also the Stoics received their lessons; whence their name, from *στοα, a porch.* Amongst other things, the Pœcile was adorned with a picture of the siege and sacking of Troy, another of the battle of Theseus with the Amazons, and a third of the fight between the Lacedæmonians and Athenians at Œnoe in Argolis. It was also accounted a great distinction to have one's portrait placed in this national gallery. In fact, the only reward which Miltiades obtained after the battle of Marathon, was to have his picture drawn more conspicuously than those of the rest of the officers who fought with him on that occasion, in the representation which was made of the engagement, and to have it hung up in the Pœcile in commemoration of that celebrated victory. This was accounted glory enough for so great and memorable an achievement.

PŒSTUM, or Pæstum, a celebrated city of Italy, now in ruins, but anciently a place of great opulence and magnitude. Its remains stand on a fertile plain, considerably to the south of the city of Salerno, being bounded on the west by the Tyrrhenian Sea, and about a mile distant by five hills, amongst which the town of Acropoli is embosomed; on the north by the Bay of Salerno; and on the east by two hills, which still retain their ancient names of Callimara and Cantena. The walls of the city remain. In some places they are five, and in others twelve feet in height. They are formed of solid blocks of stone, and appear to have been furnished with towers at intervals; but the archway of only one gate stands entire. This rampart encloses a space of about four miles in circumference; but of the splendid cluster of buildings which it once enclosed, only three temples rise, like the mausoleums of the ruined city, dark, silent, and majestic, to attest the ancient magnificence of the place. They are the admiration of all who visit them, and are considered as the purest and most perfect specimen in existence of the foreign Doric order of architecture. The first temple which presents itself to the view of the traveller is the smallest. It consists of six pillars at each end, and thirteen at each side, counting the angular pillars in both directions; and it is one hundred and seven feet in length, by forty-seven feet in breadth. The architrave is pretty entire, as is the pediment at the west end, with the exception of the corner stones and triglyphs, which are fallen, and the first cornice, which is worn away. At the east end, part of the pediment remains, and also much of the frize and cornice. The cella occupied more than one third of the length, and had a portico of two rows of columns, the ruins of which, now overgrown with vegetation, encumber the area of the temple.

The second edifice has six columns at each end, and fourteen on each side, including those of the angles. The entablature and the pediments are entire. A double row of columns adorned the interior of the cella, and supported each another row of small pillars; the upper being separated from the lower by an architrave only, without frize or cornice. A number of these pillars on each side remain standing. The cella had two entrances, one at each end, with a portico formed of two pillars and two antæ. The foundation and part of the wall of this cella still remain: underneath it there was a vault. The third edifice is the largest, being one hundred and ninety-five feet four inches in length, by seventy-eight feet ten inches in breadth. It has nine pillars at each end, and eighteen on each side, including the angular columns as before. Nor is its size its only claim to distinction. A row of pillars, extending from the middle pillar at one end to the middle pillar at the other, divides it into two equal parts, and is considered as a proof that it was not a temple. What it was intended for is yet a disputed point amongst the learned. In the centre there appears to have been an aperture in the pavement, and at some distance another, both leading, it is said, to subterranean vaults.

Such appear to be the peculiar features of each of these edifices. They are all raised upon substructions forming three gradations (for they are too high to be called steps), intended solely to give due elevation and relief to the building; the columns of all rise without bases from the uppermost of these degrees. They are all fluted, between four and five diameters in height, and taper as they ascend about one fourth; the capitals of the whole are very flat and prominent; the intercolumniation is a little more than one diameter; the order and the ornaments in all are the same; the pediment is almost invariably low; and, finally, they are all built of a porous stone, of a light or rather yellow-grey colour, and in many places perforated and worn away. In the open space between the first and second temple there were two other large edifices, built of the same stone, and of nearly the same size; but they are totally overthrown. All these temples stand in a line, and border a street which ran from gate to gate, and divided the town into two nearly equal parts. A hollow space, scooped out in a semicircular form, seems to be the traces of a theatre; and as it lies in front of the temples, gives reason to suppose that other public buildings might have ornamented the same side, and made it correspond in grandeur with that opposite; in which case few cities could have surpassed Pœstum in the splendour of its appearance.

Although the city has left such magnificent monuments of its existence, considerable obscurity hangs over its origin and general history. According to the learned Mazzochi, Pœstum was founded by a colony of Dorians, from Dora, a city of Phœnicia. It was first called Posetan or Postan, which in Phœnician signifies Neptune, to whom it was dedicated; but it was afterwards invaded, and its primitive inhabitants expelled, by the Sybarites. This event is supposed to have taken place about five centuries before the Christian era. Under its new possessors the city assumed the Greek appellation Posidonia, of the same import as its Phœnician, because it was a city of great opulence and magnitude, and is supposed to have extended from the present ruin southward to the hill on which stands the little town of Acropoli. The Lucanians afterwards expelled the Sybarites, and checked the prosperity of Posidonia, which was in its turn deserted and left to moulder imperceptibly away. Vestiges of it are still visible all over the plain of Spinazzo or Saracino. The original city then recovered its ancient name, and not long afterwards it was taken and colonized by the Romans. From this period Pœstum is mentioned almost solely by the poets; indeed, from Virgil to Claudian, they all delight to expatiate upon the beauty of its gardens, and to celebrate the bloom, the sweetness, and the fertility of its roses; and to this day the roses are remarkable for their fragrance. A few bushes, the remnants of *biferi rosaria Pœsti*, flourish here and there neglected, and still blossom twice a year, in May and December, as if to support their ancient fame, and justify the descriptions of the poets.[1] Pœstum was subsequently plundered by the Saracens and the Normans; and its remaining inhabitants were at length compelled to flee for refuge to the mountains. The Dorians appear to have the fairest claim to the erection of the majestic monuments which we have described. "But at what period were they erected?" says Mr Eustace. "To judge from their form, we must conclude that they are the oldest specimens of Grecian architecture now in existence. In beholding them and contemplating their solidity, bordering upon heaviness, we are tempted to consider them as an intermediate link between the Egyptian and Grecian manner, and the first attempt to pass from the immense masses of the former to the graceful proportions of the latter. In fact, the temples of Pœstum, Agrigentum, and Athens, seem instances of the commencement, the improvement, and the perfection of the Doric order." (R. R. R.)

---

[1] Virgil and Ovid just mention the Pœstan roses; Propertius introduced them as an emblem of mortality; Claudian employs them to grace a complimentary comparison. Ausonius alone presents them in all their beauty and freshness.

Vidi Pœstano gaudere rosaria cultu
Exoriente novo roscida Lucifero.

POETRY.

Definition.

THE difficulty of giving a definition of poetry, which shall include all that essentially belongs to it, and exclude all that is foreign or accidental to it, has been long felt and admitted. The definition of the ancients, which makes poetry "an imitative art," is obviously exposed to the double objection of being at once too comprehensive, since it would equally apply to the other imitative arts of painting and sculpture; and too limited, since it would exclude many departments of poetry, in which, as in the lyrical, the art is not properly *imitative*, but *expressive;* not copying in any sense the thoughts and actions of others, but presenting to the sympathy of the reader the emotions of the poet himself. Not less objectionable is the definition, that poetry is "the art of expressing our thoughts by fiction;" which, while it is equally applicable to the novel and the romance, is, in fact, not necessarily true of poetry at all, except in this sense, that in all high poetry a certain transforming and beautifying power of imagination is excited, which in some measure transmutes the forms of things from their actual prosaic aspect,

> Clothing the palpable and the familiar
> With golden exhalations of the dawn.

Still less can verse or metrical form be regarded as constituting the essence, or even one of the essentials, of poetry. It no doubt heightens its effect; it increases its charm and power of pleasing, by enlisting the aid of musical sound and cadence on the side of imaginative language or touching sentiment; but it must yet be regarded as amongst the externals of poetry,—something which will never make poetry of itself, and without which poetry is not only conceivable, but has in fact existed, and that in very striking and impressive forms.

Object of poetry the communication of intellectual pleasure.

Poetry may perhaps be defined to be an art which has the creation of intellectual pleasure for its object, which attains its end by the use of language natural in an excited state of the imagination and the feelings, and generally, though not necessarily, formed into regular numbers. The proper antithesis, therefore, to poetry, as Mr Coleridge has remarked, is not prose, but science. The proper antithesis to prose is verse. Science seeks to instruct, to discover and to communicate truth; "the proper and immediate object of poetry is the communication of immediate pleasure." Poetry may indeed incidentally instruct, as science may indirectly communicate pleasure; but the object of each must be gathered from its main direction and bearing, and in this sense the production of intellectual *enjoyment* is unquestionably the aim and the proper province of poetry.

This a pleasure conducive to morality.

But so closely are the intellectual and refined pleasures of man connected with his moral qualities; so much does his relish for the higher and more spiritual pleasures of the imagination depend on a sound and healthy state of morality in the first instance, and so much is this state in turn promoted and encouraged by stimulating and keeping alive the activity of the imagination and the sensibilities of the heart, that poetry, though generally avoiding the form of direct instruction, may yet be said, with justice, to be the most important handmaid and assistant of moral education, by its appeals to those affections which are apt to become indolent and dormant amidst the commerce of the world, and the revival of those purer and more enthusiastic feelings which are associated with the earlier and least selfish period of our existence. Immersed in business, which, if it sharpen the edge of intellect, leaves the heart barren; toiling after material wealth or power, or struggling with fortune for existence; seeing selfishness reflected all around us from the hard and glittering surface of society, as from a cold and polished mirror; it would go hard with man in adversity, perhaps still more in prosperity, if some resource were not provided for him, which, under the form of an amusement and a recreation, administered a secret but powerful balm in the one case, and an antidote in the other. This resource is afforded us by the influences of poetry. "Whatever withdraws us from the power of the senses; whatever makes the past, the distant, and the future, predominate over the present, advances us in the dignity of human beings." Sometimes, no doubt, poetry openly assumes the garb of morality, but it is generally least instructive when most directly *didactic*, and practically attains the end of instruction with most success when the instructor is himself unconscious of the lesson he conveys. In an indirect form, however, and through the medium of the feelings and the imagination rather than the mere reason, its efficiency as a moral agent is great and undeniable. And as upon the intellectual worth and nobleness of individuals depends the standard of a national morality, it may with truth be said that the fame and character of nations,—those qualities the presence of which makes the smallest state conspicuous in the world's eye, and the absence of which renders the widest empire, on which the sun never sets, insignificant; namely, national pride, honour, fidelity to engagements, courage to act, fortitude to suffer, a generous and far-seeing policy, disdaining all mean or questionable advantages; are to some extent derived, and, at all events, continually cherished and fostered, by the influence of a pure and ennobling national poetry. If Plato had succeeded in banishing poets from his ideal republic, he would assuredly have conferred no benefit upon morals. He would have created a hard and utilitarian frame of society, inaccessible to generous feeling, and incapable of those great efforts, either of action or of endurance, which have their source only in enthusiasm, and cannot be suggested by any principle of expediency, however enlarged may be the basis of calculation.

No poetry permanently popular which is of an immoral nature.

It is the conviction of this intimate though indirect connection between poetry and morality, and the consequent bearing of the former upon human welfare, that explains the veneration which mankind have always felt for those poets who, acting under an impression of the sacredness of the task committed to them, and of the power of the talisman which genius has placed in their hands, have devoted their labours to the purest forms of poetry, and to the excitement of emotions, either virtuous in themselves, or conducive to virtue. It is this conviction which accounts for the aversion which they have never failed in the end to manifest against all those who have made the fascinations of poetry and wit subservient to the gratification of baser feelings or meaner propensities. For men taken in the mass judge rightly, even when they act wrongly; and moral opinion, so variable and wavering when applied to our own case or that of our friends, is found a safe and steady guide when applied to the mere *representation* of human thought and action in the forms with which they are invested by the poet. Hence the feelings of all men are enlisted and warmly excited on the side of virtue in fictitious composition, and still more in the most fascinating form of fictitious composition, poetry. For here the *tendency* of the poem is felt to be no mere speculative question, but a real dispute "pro aris et focis;" a contest whether, as is said to be often the case in India, poison is to be conveyed into the wells from which pure and refreshing water ought to be drawn. And this practical bearing upon important interests, of the abuse of a fine art, is more felt, and justly, in poetry than in any other. In painting, for instance, Parrhasius, Julio Romano, Annibal Caracci, and Titian, have ministered by their pictures to the promotion of vice; some have even endeavoured to pervert the pure marble into a vehicle of impure representations: but the circle of their operation is limited; to the mass of men their iniquities of this nature are even unknown: but poetry, multiplied indefinitely by printing, finding its way into every quarter of the globe, and penetrating into the humblest as well as the highest class of society, has a sphere of operation bounded only by the globe itself, and a practical influence, through their sympathies, upon men's habits of thought, and consequently upon their morality and their happiness, which is not the less certain and extensive, that its limits do not admit of any precise or distinct determination.

Hence it is a remarkable fact in the history of poetry, that no work essentially immoral, or even exhibiting a mere indifference to moral feeling, has ever maintained a permanent popularity. The low ribaldry which deforms the splendid talents of Aristophanes will always render the perusal of his plays a painful task; the witty licentiousness of the Pucelle is already all but forgotten; and the next generation, while they treasure the better parts of Byron, will assuredly consign to oblivion much of his gloomy reasonings, his contempt for human nature, and his ridicule of generous feelings. The poets who are found to retain their hold over all hearts, and whose influence even appears to extend with the progress of ages, Homer, Shakspeare, Milton, Spenser, Calderon, Tasso, are those who have done their utmost to elevate rather than to depress the spirit and the hopes of men; to make existence brighter about us, and to embody in their strains the principles of faith and hope, of purity and universal charity. For it need hardly be observed, that we are not to condemn a work as immoral on account of a few brief passages, in which the poet, led away by a too lively imagination, has admitted scenes or images of an objectionable kind. Such, indeed, are to be found in Shakspeare, and in the pure and religious poems of Spenser; more rarely also in Tasso; but the general strain of the poem, and the obvious aim of the poet, being to promote the cause of virtue, the few objectionable particulars are lost in the general effect, and cease to be dangerous from their proximity to so much that is calculated to purify and to elevate the mind.

h.

If it be difficult to give an accurate definition of poetry, it is still more difficult to describe that precise combination of mental and moral qualities which are required for its production, so as to distinguish these from the qualities required for perfection in the other imitative arts. The sensibility to natural and moral beauty; the study both of the outward world and of the mind of man; imagination and fancy to furnish the materials; judgment and taste to select and arrange them; these are common to the great poet and the great painter. What determines these energies and capabilities to the one direction more than to the other, and makes one man paint to the bodily eye in cólours, the other to the eye of the mind in words, is that secret undefinable instinct which we call genius, which it is impossible to resolve into any mere result of the force of circumstances, and which, all experience teaches us, is born with the artist, and, like an instinct, directs his after-course. A genius for poetry or for painting is as certainly dependent on an organization mental and physical, with which we come into the world, as a musical ear; no education can give them; no general superiority of intellect will enable a man to turn with equal success to either; nature made him with the elements of a poet or a painter, and what she has so framed, art and education will never alter.

But though it is difficult to enumerate any quality requisite to form a great poet which is not necessary also to form a great painter, it is easy to see, that from the nature of the materials with which they deal, as well as their modes of operation; the one producing its effects by a momentary impression, the other by a continuous exertion; the degree in which the different component qualities of mind are employed in these respective arts is materially different.

Imagination.

Foremost amongst the qualities that constitute the poet is imagination, that creative principle of the mind which forms new conceptions out of previously existing materials; "conceptions not absolutely justifiable by the rules of logic, but quite intelligible to the mind when duly elevated; intelligible through our sympathies or sensibilities, though not sufficiently definite nor strictly coherent to stand the cold survey of our reason." This is indeed the most essential gift of the poet, "where either he must live or have no life;" with it, he may triumph over every other defect; without it, no combination of qualities will ever render him a great poet. This is the power which emancipates the poet from the trammels of space and time; carries him back into the spirit of past ages; enables him to create and to endow with coherent attributes beings of a nature different from our own, and yet having for us a real existence, so far as our sympathies are concerned: to conceive and consistently to follow out the thoughts, and words, and passions of imaginary actors, and all this not by a metaphysical analysis of the emotions or passions, nor by a course of induction from actual observation in the world about him, but by a secret consciousness, flashing upon his mind, in a concentrated shape, the result of all philosophy, embodying all, which conception, abstraction, and judgment would have separately furnished. It supersedes the necessity of observation in every special case, because it furnishes him with those primary elements of our nature which give the formula for the solution of all. The value of patient observation and study of life and character, in addition to the suggestions of the imagination, we do not dispute; we shall afterwards see, that within certain limits, and for certain departments of poetry, they are indispensable. But we may be assured, that for those elemental conceptions of character which are unmodified by mere manners, local position, or age; the conception, for instance, of a Lear or a Miranda, a Caliban, an Ariel, or a Hamlet; no observation of human character in the actual world, nor dissection of the component passions and sympathies that make up character, would have sufficed. We have but to look at the range of Shakspeare's characters to be at once satisfied of this. Pre-eminent amongst these are his characters of women; and yet from what analysis of character, or observation of society, could these have been drawn? Where could a youth, whose chief companions had been deer-stalkers, actors, or play-writers of no high repute, and to whom female society, at least in its most refined form, must have been unknown, have gleaned the materials which enable him to pourtray, with equal mastery, the fierce overbearing spirit of Lady Macbeth and Constance, the tranquil regal dignity of Hermione and Katharine of Aragon, or the totally dissimilar aspect of female character presented in the passion of Juliet, the purity of Miranda, the simplicity of Ophelia, or the tender submission and wife-like confidence of Imogen and Desdemona? No prototypes existed in the society around him from which these could be drawn. The streets and taverns of London might indeed furnish him with Bardolphs and Pistols; his acquaintance with Lord Southampton, or with the other gallants of the court, might afford the outlines of his Prince Henry or Hotspur; but his female creations are obviously drawn from no other sphere but his own breast. They are the offspring of an imagination "all compact," not elaborately constructing, but almost unconsciously creating.

The power of imagination is shown in its most imposing form in the conception of character, incident, situation, and scenery,—in the general scope and design of the poem; but its value and importance as an element of poetry is scarcely less felt in the details, in the manner in which it informs and transforms the whole language of the poem; studding it with imagery, simple or complex, often making a single word act like a spell, and conjure up a host of magical associations. Its province in this respect is not to be confounded with that lower department of the poetical art which is called diction, and which, when the idea is formed, simply dictates the selection of the *word* most appropriate to express the precise *idea* to be conveyed. Imagination supplies the idea itself, or fasciculus of ideas, to be embodied in the word; and in the number, novelty, and judicious selection of associations which can be suggested to the mind within any equal space, lies the chief difference between the work of a great poet and an inferior one, between an original or an imitative mind.

The images suggested by the imagination, we have said, are frequently complex. It seems to fuse many in one, to divide one into many, and to present the mass to the mind in a form which suggests all the particulars of which it is composed. It is certain, too, that many of the images which it suggests, and the effect of which upon the mind is immediately felt by all lovers of poetry to be beautiful, can by no means be justified upon the principles of logic, or their coherence made clear to the understanding. "When Milton tells us of 'darkness visible,'" says a writer on poetry, "we feel that he has uttered a fine paradox; we *feel* its truth, but cannot prove it. And when in that appalling passage where the poet stands face to face with Night and Chaos in their dark pavilion, 'spread wide on the wasteful deep,' and says that

> By them *stood*
> Orcus and Ades, and the dreaded *name*
> Of Demogorgon,

how is it possible to reconcile such expressions to a mere prosaic understanding? Darkness is, strictly speaking, absence of light. How then shall we say that it is visible, when we see only by the aid of light? And with respect to the '*name*' of Demogorgon, which *stands* by Orcus and Ades, how can such a phrase be justified by the rules of reason? Nevertheless it is as magnificent as words can make it. It is clothed in a dark and spectral grandeur, and presses upon our apprehensions like a mighty dream."[1] Take another instance also from Milton, where he speaks of music

> At every fall smoothing the raven down
> Of darkness till it smiled.

Here also it is impossible to perceive the mere logical connection of the images; for, allowing darkness to be embodied under the notion of some bird with glossy and raven plumage, it would certainly puzzle any critic to show how musical sounds could smooth such plumage; and yet we should have little hesitation in putting this passage to any one as a test whether he possessed a feeling or sense of poetry, or whether his mind was entirely of a prosaic character. In these, and a thousand similar instances, particularly in Shakspeare, it is clear that the poetical effect can be explained upon no ordinary principle of reason. The metaphors are what are called broken; they cannot logically be united, and yet they have a sufficient poetical coherence. How this result is produced we shall only be enabled to explain when the whole laws which govern the faculty of imagination, as yet most imperfectly understood, shall be discovered.

It is somewhat difficult to establish a plain and practical distinction between fancy and imagination, so far as regards the imagery or ornaments of poetry; though, as we have already said, the higher efforts of conception, and the general design, fall almost entirely, in serious and heroic poetry, under the province of imagination. From Milton's line, "Sweetest Shakspeare, Fancy's child," it would seem that the words fancy and imagination had then been used as having the same meaning; for certainly any one now endeavouring to describe the most remarkable of Shakspeare's qualities would refer to his imagination rather than his fancy. Yet fancy may perhaps be said to be imagination at a lower point of excitement; not dealing with passions, or creating character; nor pouring out unconsciously, under the influence of strong feeling, images as they arise massed and clustered; but going in search of comparisons and illustrations, and when it invests them with personality, as in metaphors, still adhering much more closely to the logical fitness and sequence which govern similar ornaments in prose. It seems to act like a colder and weaker species of imagination, furnishing the thoughts which "play round the head, but do not touch the heart;" pleasing the eye and the ear; creating or heightening the idea of the beautiful, much more than of the sublime. It is not careful, like imagination, to make the whole bear on the general design, and heighten the main impression sought to be produced, but rather strives to excite our pleasure, and to bespeak our admiration for the images themselves which it suggests. Its natural field, so far as regards the general design, is in poems like the Rape of the Lock, or the Lutrin, where the object is to give a poetical dress to a subject essentially prosaic, and excluding passion or high imagination. To these it lends an airy machinery, ingenious comparisons, imagery of a lively and pleasing cast in harmony with the level tone of the subject, and thus brings them within the domain of poetry. Some have represented the distinction between the effects of imagination and fancy to consist in this, "that the former altogether changes and remodels the original idea, impregnating it with something extraneous; the latter leaves it undisturbed, but associated with things to which, in some view or other, it bears a resemblance." But this distinction cannot be admitted; fancy, though in a less degree, does create, or change and remodel ideas; the difference between them must be sought more in the sort of ideas on which they operate, and the purposes to which they apply them, than in the plastic power supposed to be exercised in the one case and not in the other. "Fancy," says Mr Wordsworth, in a fine passage in his preface, "depends upon the rapidity and profusion with which she scatters her thoughts and images, trusting that their number, and the felicity with which they are linked together, will make amends for the want of individual value; or she prides herself upon the curious subtilty and the successful elaboration with which she can detect their lurking affinities. If she can win you over to her purpose, and impart to you her feelings, she cares not how mutable and transitory may be her influence, knowing that it will not be out of her power to resume it upon an apt occasion. But the imagination is conscious of an indestructible dominion; the soul may fall away from it, not being able to sustain its grandeur; but if once felt and acknowledged, by no act of any other faculty of the mind can it be relaxed, impaired, or diminished. Fancy is given to quicken and to beguile the temporal part of our nature, imagination to incite and support the eternal. Yet it is not the less true, that fancy, as she is an active, is also, under her own laws and in her own spirit, a creative faculty. In what manner fancy ambitiously aims at a rivalship with the imagination, and imagination stoops to work with the materials of fancy, might be illustrated from the compositions of all eloquent writers, whether in prose or verse, and chiefly from those of our own country. Scarcely a page of the impassioned parts of Bishop Taylor's works can be opened that shall not afford examples. Referring the reader to these inestimable volumes, we will content ourselves with placing a conceit, ascribed to Lord

---

[1] Edinburgh Review, 1825.

Chesterfield, in contrast with a passage from the Paradise Lost.

> The dews of the evening most carefully shun ;
> They are tears of the sky for the loss of the sun.

After the transgression of Adam, Milton, with other appearances of sympathizing nature, thus marks the immediate consequence.

> Sky lowered, and, muttering thunder, some sad drops
> Wept at completion of the mortal sin.

The associating link is the very same in each instance ; dew and rain, not distinguishable from the liquid substance of tears, are employed as indications of sorrow. A flash of surprise is the effect in the former case ; a flash of surprise and nothing more ; for the nature of things does not sustain the combination. In the latter, the effects of the act, of which there is this immediate consequence and visible sign, are so momentous, that the mind acknowledges the justice and reasonableness of the sympathy in nature so manifested; and the sky weeps drops of water, as if with human eyes, as earth had before trembled from her entrails, and nature given a second groan." It is evident, that in the parallel passages thus opposed to each other by Wordsworth, the creative or remodelling operation produced by fancy in the former case, and by imagination in the latter, is the same ; in both the sky is endowed with personality and human feeling ; it is the propriety of the action attributed to the imaginary being in the one case, and its unreasonableness in the other, which makes the former merely fanciful, the latter highly imaginative.

Danger of an excess of fancy.

It will readily be perceived, from what has here been said of the nature of fancy, that when unregulated by a strong judgment, and unwarmed by strong passion, it is one of the most dangerous qualities which a poet can possess. To the predominance of this quality, indeed, to the consciousness of a facility of finding ingenious analogies or subtile distinctions, of conjuring up a multitude of fantastic resemblances, pleasing in themselves, but in no way heightening the leading impression sought to be conveyed, are to be ascribed many of the errors of taste by which modern poetry has been deformed. To this must be ascribed those conceits, from which scarcely a single Italian writer prior to the eighteenth century is free, and which reached their consummation in Marino ; to this the similar extravagancies of Gongora, Quevedo, and their followers in Spain ; the affected taste introduced by Voiture and Balzac in France, and exploded by the good sense of Molière ; and the similar extravagancies of our own metaphysical poets. An excess of imagination cannot lead to bad taste in style ; an excess of fancy is but too apt to produce that effect.

Judgment.

Of judgment, which is the regulating and controlling power by which the active and creative faculties of imagination and fancy are guided, checking the too daring flight of the one, and pruning the excesses of the other, it is needless to speak ; since it is a quality not more peculiarly requisite in poetry than in oratory, or any of those departments of intellectual exertion which depend not on demonstration, but on the balance of probabilities. In fact, the highest range of imagination has invariably been found to be accompanied by a corresponding depth and comprehensiveness of judgment ; or rather, perhaps, it would be more philosophical to say, that judgment is involved and constitutes one of the component parts of high imagination. For the imagination, as is justly remarked by Mr Stewart, is a *complex* power. " It includes conception or simple apprehension, which enables us to form a notion of those former objects of perception or knowledge, out of which we are to make a selection (in the fine arts) ; abstraction, which separates the selected materials from the qualities and circumstances which are connected with them in nature ; and judgment or taste, which selects the materials, and directs their combination." It is only in minds where imagination is limited, and where its possessor tries by effort and straining to enlarge it beyond its appointed bounds, that the judgment is generally found defective. Homer and Shakspeare, the most inventive and imaginative of poets, are also the most sagacious, the most practical, the most abounding in wisdom, both of a worldly and of a higher kind.

Study necessary to form a poet.

But, in addition to the natural gifts of sensibility to feel, memory to retain impressions, imagination and fancy to fashion new conceptions, and judgment to blend in harmony all the materials which have been thus accumulated, study is just as essential for the formation of the poet as for the acquisition and practice of the most mechanical art. That study regards both the materials of poetry and the language by which they are to be communicated in a sensible form to others. Study of men in the different conditions of life, and the habit of observing and systematising these observations ; study of external nature, so as to mark the peculiarities which escape common eyes ; the accustoming the mind to search for resemblances among things different, and to lay them up in the memory as in a treasury ; these are assistances which no poet can overlook, and without which the imaginative faculty is deprived of its due nourishment, and of half its power. For even imagination does not strictly create out of nothing ; it must be quickened and set in motion by something external, and demands materials on which it can try its processes of change or recombination. All great poets, therefore, have steadily pursued this course of study of nature, both moral and physical ; though, after the habit is once formed, these mental operations are carried on almost unconsciously, and the treasures of poetical observation grow upon their possessor, without his being conscious of any effort in their accumulation. A remarkable instance of the attention paid by great poets to the minutest peculiarities of external nature, and of course equally applicable to the study of mental phenomena, is afforded by the case of Sir Walter Scott. Every one knows the graphic truth as well as the wonderful variety of his descriptions of scenery, which, by their selection of every thing that is characteristic, embody the very spirit of the place, and call back to our minds the impression with which we had first viewed it, and which had faded away and become forgotten. It is evident that in such descriptions Scott trusted little to the imagination, as able to compensate the observation of reality. Mr Morritt mentions, that whilst he was engaged in the composition of Rokeby, he observed him noting down even the peculiar little wild flowers and herbs that accidentally grew round and on the side of a crag near his intended cave of Guy Denzil ; and on his saying that he need not have taken the trouble, since daisies, violets, and primroses, would have suited his purpose as well as the humble plants he was examining, the poet replied, " that in nature herself no two scenes are exactly alike, and that whoever copied truly what was before his eyes, would possess the same variety in his descriptions, and exhibit apparently an imagination as boundless as the range of nature in the scenes he recorded ; whereas, whoever trusted to imagination would soon find his own mind circumscribed and contracted to a few favourite images, and the repetition of these would, sooner or later, produce that very monotony and barrenness which had always haunted descriptive poetry in the hands of any but the patient worshippers of truth."

Diction.

The other department of the poet's study relates to the use of the medium through which his ideal creations are to be conveyed to others ; in other words, diction, or the choice and arrangement of the words most appropriate to convey the precise shade of meaning, and to convey it divested of all those associations of a low or ludicrous character, which usage sometimes connects with words, and assisted by all the charms of musical sound. All men who seek to command the minds of others through speech must by study learn to apprehend the power and perfect force, as affecting thought, imagination, and passion, of every word which his fellow-men have used for ages as the vivid image of some conception of the soul. They must acquire a perception of the value of words, at once exact, delicate, and passionate. This careful and fond study of language, however, is peculiarly requisite to the poet, and has been carried to higher perfection by them than by prose writers; "because, in the composition of poetry, the mind, attempered to delight, feels more sensitively the exquisite form into which the material expression of its conception is wrought." The very shackles imposed by metre and rhyme, though they may occasionally tempt an inferior poet into the use of a word which is not the one most apt to express his conception, unquestionably only operate as a stimulus to the great poet to make himself master of all the resources of words which the language supplies, so as to comply with the necessities of rhyme and musical sound without sacrificing any portion of the substance of his conception. Without this thorough command of the whole armament of language, and the utmost patience and perseverance in its use, we may be assured that no poet has ever succeeded in attaining a general and permanent popularity. Verse cannot leap full armed from the brain of the poet. The steps which lead from the rudeness of the first conception to the elegance of the last, though they cannot be seen, are undoubtedly many. The ideas must be patiently wrought into shape; words weighed and rejected; shades of meaning of the nicest kind discriminated; associations foreseen and guarded against; and an arrangement of words throughout preserved, which, while it differs from that of prose, never allows the inversions which are admitted in poetry to obscure the meaning. The practice of the greatest poets we know to have been in conformity to these rules. We find Virgil dictating a number of verses in the morning, spending the day in revising, correcting, and reducing them, and comparing himself, as Aulus Gellius mentions, to a she-bear licking her misshapen offspring into shape. We see Petrarch returning day after day to his sonnets, to alter some single word, or make some trifling change in the arrangement of a line. The manuscripts of Ariosto, whose style appears the very perfection of ease, and an almost spontaneous emanation, still exist at Ferrara, and show that many of the favourite passages in the Orlando were written eight times over. Scarcely less attention was bestowed upon the stanzas of the Gerusalemme by Tasso. Milton's study of English speech, and mastery of the artifice of language, as well as the critical care with which he built up "the lofty rhyme," are well known.

> He with difficulty and labour hard
> Moved on; with difficulty and labour he.

The specimens of Pope's Iliad given in Johnson's Life, exhibiting the successive changes which the lines underwent before they assumed that compact and harmonious form in which they appeared before the public, must be in the recollection of every reader. And we see from the letters of Lord Byron, that the same laborious process of polishing was not disdained even by his impetuous mind. It is indeed scarcely too much to say, that no composition of any length, which has attained a permanent popularity, was ever thrown off at a heat; and that the nearer the work approaches to the appearance of spontaneity, the greater has in general been the extent of the labour which has been employed upon it.

Qualities common to all good poetry.

Such being the qualities and habits of mind that make the poet, it may be asked what are the common qualities to be found in all poetry which has permanently commanded the admiration of mankind. Milton has endeavoured to condense these into a sentence. Poetry, he says, must be "simple, sensuous, passionate."

Poetry must be simple.

By the first quality, simplicity, which applies both to the matter and the language, he seems to indicate the necessity of dealing in poetry with the simple elements of human nature; keeping the broad highways of feeling, avoiding affectation of sentiment, over-refinement, or morbid peculiarity of any kind. "It distinguishes poetry from the arduous processes of science labouring towards an end not yet arrived at, and supposes a smooth and finished road on which the reader is to walk onward easily, with streams murmuring by his side, and trees, and flowers, and human dwellings, to make his journey as delightful as the object of it is desirable, instead of having to toil with the pioneers, and painfully to make the road on which others are to travel."[1] And unquestionably it is the fact, that the works of the greatest poets are the simplest, the most level to ordinary apprehension, the most adapted to ordinary sympathies. Homer, in whose works nature is reflected without change, is understood and relished equally by the youth and the man, by nations the most distant from each other both in space and time. Shakspeare, in like manner, in whose works we can detect no subjective influence produced by his own mind, and who seems to range like the universal sun over the provinces of emotion, enlightening all alike, produces the same deep impression on the learned and the unlearned. Both concur in this, that they do not paint the exceptional, but the customary; not the peculiarities, but the common features of humanity; and that they paint these broadly and simply, instead of endeavouring, by a complex apparatus of singular traits and colours, to display their own artistic skill.

Sensuous.

The second of the qualities enumerated by Milton is, that poetry must be "sensuous;" that is, that it shall have that character of sensible reality, which shall prevent its degenerating into mere dreams and abstractions; that it shall be so far connected with the world about us, and with our actual interests and pursuits, as not to appear altogether the creature of another sphere; and this both as to the nature of the subject and the definite nature of the imagery employed upon it. The right understanding and application of this rule would have saved the world from many of those hazy poetical abstractions, or attempts to transmute political or metaphysical theories into poetry, with which, in the present age in particular, the public has been inundated. It is the neglect of it which renders the metaphysical poetry of the sixteenth century, with all its grandeur and force of thought, so often unreadable; which has made the poetry of Keats, abounding, as it does, in exquisite beauties of conception, a sealed book to the mass of readers; and which, more even than its irreligious tendency, has obstructed the popularity of the poems of Shelley.

Passionate.

The third requisite of poetry is that it be passionate. It is not enough that thought and imagery be sensuous, or objective and definite; the *passio vera* of humanity, as Coleridge remarks, must animate both. It is by our sympathies that poetry lays its strongest hold on us; and it is by the representation of passion that these must be set in motion. Even the lower and more level departments of poetry must be warmed by it; of the epic, and still more the dramatic, it constitutes the mainspring. Didactic and descriptive poetry would become wearisome were they not enlivened by the occasional introduction of scenes awakening the feelings of love or pity. In lyric poetry, the song constantly exhibits its condensed expression; in fact, so powerful is its influence, that genuine passion will often support a poem which has but slender claims to fancy or imagination. The mere literal and truthful exhibition of the greater passions of our nature so stirs within us the sense of the sublime or the terrible, so rouses our curiosity and suspense, that for a time we are willing to dispense with the more ethereal colouring which imagination might impart to them. We say, however, for a time only; for a literal picture of human passions, if prolonged through a whole drama, and unrelieved by imagery, or the expression of calmer thought, is felt to be painful and harrowing to the mind. Such is the effect produced by the Newgate Calendar dramas of Lillo, George Barnwell, Arden of Feversham, and the Fatal Curiosity, and by the similar tragedy of Werner, the Twenty-Ninth of February. So great was the effect produced by the scene in Lillo's play representing the murder of Arden, that the audience, unable to endure the excitement of the representation, rose up with one accord and interrupted it. Appeals to our passions, presented in this bleak and naked reality, have the same painful effect upon the mind which exhibitions of crime and suffering have in real life. To make them produce a pleasing effect in poetry, at least for any length of time, they must be blended with associations of a less vulgar and less agitating kind; and the pain which attends our sympathy must be tempered by the soothing imagery suggested by the imaginative and reflective faculties.

The qualities enumerated by Milton may be considered as fixed and inherent in all good poetry; beyond these it is difficult to point out any which are of permanent and universal necessity. That poetry which seeks to please through our sympathies must shift and vary, both in its themes and in the manner of treating them, with the changes of society, is a truism on which it is needless to enlarge. If the opinions of men change, if their habits and the objects and associations which interest them alter, poetry must adapt itself to this altered state of things. It does so indeed unconsciously; it cannot avoid doing so, for the poet's own nature has partaken of the change.

poetry.

It is a more important question, whether the progress of society, the advancement in civilization, and the moral habits and intellectual constitution which accompany it, operate favourably or unfavourably on poetry; in other words, Is there reason to believe that the imaginative faculty in poets, and the sensibilities of their readers, decline with the progress of refinement in the arts; or that the imagination no longer finds the same materials in actual life on which its plastic power can be excited?

The tendency of most of the late inquiries into the question has been towards the opinion of its unfavourable influence. The faculty of imagination is supposed to decline as knowledge becomes more exact; the turn for analysis, which is the characteristic of advancing civilization, and which shows itself in the philosophical character which language assumes, is maintained to be destructive of that individuality and distinctness which is the life of poetry; substituting general abstractions for particulars, vague phrases instead of images, and personified qualities instead of men. In a half-civilized state of society, too, life is a romance, a tissue of adventures, powerfully exciting the feelings of fear, wonder, and enthusiasm. In more refined periods these sources of excitement cease; and, even where they exist, they are veiled by the caution which the fear of ridicule produces, a restraint which in the ruder periods of society is comparatively unknown. Hence both the imagination of the poet and the sensibilities of the reader of poetry are chilled. "Poetry," says one of the ablest exponents of this unfavourable view of the effects of civilization on the arts, "produces an illusion on the eye of the mind, as a magic lantern produces an illusion on the eye of the body. And as the magic lantern acts best in a dark room, poetry effects its purpose most completely in a dark age. As the light of knowledge breaks in upon its exhibitions—as the outlines of certainty become more and more definite, and the shades of probability more and more distinct—the hues and lineaments of the phantoms which it calls up grow fainter and fainter. We cannot unite the incompatible advantages of reality and deception, the clear discernment of truth and the exquisite enjoyment of fiction."

Yet these observations, though true to some extent, must be received also with some qualification. If language loses something in picturesqueness, it becomes far more pliant, far better adapted to convey the exact idea intended; if phrases which originally conveyed images have by long use ceased to be metaphorical, we see that genius is constantly creating and giving currency to new combinations. Knowledge and learning and mechanical improvements, if they tend to repress enthusiastic feeling, at least supply poetry with a host of illustrations unknown to earlier periods; but, above all, it may be doubted whether the enthusiastic and imaginative faculties within us can ever be materially affected by the changes of society, however their outward manifestations may be repressed. Whilst men feel that they are connected with eternity, mysteriously surrounded by influences which they feel and acknowledge though they cannot account for them; whilst love still holds a place in the heart, and carries the spirit of romance into the barest realities of existence; whilst men have a country to honour and defend; whilst they can still be animated to enthusiastic concert in the cause of humanity; whilst the strange accidents by which even our decorous and conventional course of life is at times broken, still present to them a thousand scenes of joy or calamity; there seems little reason to apprehend that the imaginative faculty can ever be so impaired from want of external nutriment or inward vigour, but that a truly great poet will always find the means of speaking to the hearts and sympathies of men, in different language it may be, but with undiminished power.

Still less reason is there for the apprehension, that the materials for description and illustration which external nature offers to the poet are likely to be in time exhausted, or even materially encroached upon. Certainly the first and the more obvious of its features are caught by the first labourers in the field of poetry, with a truth and liveliness which no subsequent efforts are likely to surpass; and if poetical imitation were, like literal landscape or portrait painting, a mere transcript of the scene before us, there might be reason to think that all the more striking aspects and points of view would, in the course of time, come to be exhausted, and the poet driven either to mere repetition in a feebler form, or to seek for novelty by endeavouring to turn to account the materials which his predecessors had thrown aside as least fit for their purposes. But when it is recollected how infinite are the varieties and combinations of which the objects of moral and material nature are susceptible, how largely, too, a creative and changing power is exercised in poetical imitation; and in how many different lights, independently of this process of imaginative change, the objects around us are placed by natural differences of associations in the person who contemplates them; it may be safely assumed that the materials of poetry are inexhaustible.

That poetry must have existed from the very earliest periods is undoubted. As the expression in language, of that feeling of excitement and elevation produced either by moral or material grandeur or beauty, it had its seat and origin in human nature itself, and in its simplest form must necessarily have existed as soon as man felt the desire of recording his impressions, or communicating them to others. In its first shape it may have been destitute either of rhythm or metre; although so close is the connection between that state of the imagination which gives birth to poetical conceptions, and a tendency to assist the effect of these by certain intonations of the voice approaching to musical sounds, that it is far more probable that even from the first something of measure was imparted to it, probably without effort or consciousness on the part of the reciter. At any rate, the power of measure as an assistant to memory, and as furnishing a species of gratification to the ear, apart from the mere effect of the ideas upon the mind, could not fail to be soon perceived and acted upon. At first, in fact, poetry and music seem to have been constantly associated; for the study of music, as something separate from the accompaniment of words, is one which arises only at a later period; and in all the poetical compositions which have descended to us, the elements of versification, or division of lines into certain measures, are discernible.

HEBREW POETRY.

The poetry of the Hebrews is the oldest in the world. It stands apart from all the rest, in solitary grandeur, like a pillar of fire in the poetical wilderness. The poetry of Greece, for instance, only begins to exist centuries after the noblest efforts of the Hebrew muse had been produced and committed to writing. Even the oldest poetry of the Arabians, whose language is a kindred one to the Hebrew, is of far more recent date than the Jewish Scriptures, in fact not much older than the time of Mahommed. The Hebrew poetry, as it has come down to us, seems limited in its field, though within that field it has attained a mastery never excelled. Almost all its compositions are lyrical, and chiefly in the highest department of the lyric, resembling, though in a less regular and artful form, the ode of the classical poetry. Its characteristics appear to be unequalled majesty of thought and expression, a fervour and flow which, more than in any other poetry in existence, suggest the idea of an inspiration or divine afflatus, dictating, through the poet as a mere organ, the sublimest ideas in words of corresponding weight and grandeur; a profusion of imagery and illustration, which, though it at first appears excessive and overpowering to the critic of modern times, and colder climes, is seen upon further study to be in the closest harmony with the Hebrew character, and that of all the oriental nations, and is remarkable for the absence of any thing farfetched or elaborate; a rapid desultory movement from one train of thought or illustration to another, without formally supplying the links in the chain of association which have led to the new topic,—as if the poet relied upon a corresponding excitement in his readers or hearers to supply that elevation and reach of poetical vision necessary for tracing the chain of ideas from first to last. It is certain, however, that to the Hebrews themselves there was much less of abruptness and want of connection in their lyrics than at first sight appears to us; and that slight hints were sufficient to awaken trains of associations to which, from our altered circumstances and character of mind, we have now no clue; and this observation, in fact, applies equally to the Hebrew and to great part of the classical poetry of Greece and Rome.

Circumstances from which it derived its peculiar character.

When we look to the Hebrew character and poetry, and to the local situation and manners of the country, we perceive a combination of circumstances highly favourable to the growth and development of that department of poetry in which alone they can be said to have attained distinguished eminence. All the elements out of which a great national lyric poetry is formed existed amongst the Hebrews, both as regarded the impulses of the mind and the external influences by which they were surrounded and daily acted on. They had been selected as God's peculiar people from among the nations; they held as it were a commission from heaven, giving them authority over the world; they looked upon themselves as the race from which its Saviour was to spring. They had triumphed, by the divine aid, over the kings, and princes, and Pharaohs of the earth; they had the recollection of all their strange wanderings, their miraculous deliverances, their acquisition of the promised land, and their law given amidst audible thunders and visible smoke from Mount Sinai, in the presence of assembled myriads. They had a religion which, excluding the worship of the Deity under visible symbols, only made the image of the Deity more deeply and impressively worshipped within the temple of the heart and the imagination: while the connection of religion with all the affairs of life; the constant rites and ceremonies and festivals of rejoicing or humiliation; the presence of the Deity, kept before their thoughts by the ark, which was supposed to be his peculiar seat, and the sacredness of which had been more than once guarded or avenged by prodigies; prevented that religion from becoming a mere abstraction, and gave to their conceptions of the Deity a warmth and life peculiarly suited to the poetry of devotion, as blending the ideas of the visible and the spiritual, without any admission of those palpable, material, and degrading conceptions which mingle with and deform, to our associations, the mythological or religious poetry of Grecian polytheism. No commercial pursuits tended to excite among the earlier Hebrews the prosaic love of gain. They were shepherds, husbandmen, or warriors, deriving subsistence from the soil, and attached to it by a train of recollections. Frequent public ceremonies, festivals, jubilees, gave occasion for the assemblage of the people in large masses, for a common purpose; the occasion of all others most likely to call forth, by a common sympathy, the enthusiasm which stimulates the imagination into poetical activity. Add to these a climate bright and cheerful, but admitting also of every variation and interchange of serenity or tempest; a country, the external aspect of which presented the strongest contrasts of barrenness and luxuriance; fertile plains, with mountain ranges of the most bleak and desolate grandeur; gardens like those of Damascus, with dreary lakes like the Dead Sea, whose stagnant waters still spoke of the fall of the cities of the plain, or wildernesses haunted by the lion, the rhinoceros, and the serpent; and it would indeed be matter of surprise if the Hebrew sacred poetry were not characterized by a remarkable feeling of national pride, of sublimity, simplicity, and natural pathos in its sentiment, and by a peculiar freshness, truth, and boldness in its pictures of nature, or illustrations derived from external scenery. The parched plains of Judæa, the rocky top of Sinai, the towers of Damascus, and the gardens of Lebanon and Carmel, supply them with figures or allusions which have an unspeakable charm of picturesqueness and beauty. The climate is vividly brought before us in the allusions to the wellsprings that water the desert, and to the shadow of the great rock in a weary land. We see the simple character of their life in their pastoral images, so constantly derived from the tending of flocks and herds; imagery so congenial to their minds, that it is employed by the Author of our faith in some of the most touching passages of the New Testament. Such is the character of those books of the Hebrew Scriptures which are on all hands admitted to be poetical, though we know too little of the laws of Hebrew prosody to be able to say whether they are written in verse, though a species of rhythm, and apparent equality in the divisions of portions of the sentences, appear to indicate that they are. Such are the Book of Psalms; one of which (the ninetieth) is even ascribed to Moses, whilst several others were the production of predecessors or contemporaries of David. It is certain, however, that those ascribed to him are the finest and the most affecting of the whole, though perhaps not the most magnificent in point of stateliness of diction and imagery. "Nor is it in tragic so much as in joyous expression," says Mr Campbell, "that I conceive the power of his genius to consist. Its most inspired aspect appears to present itself when he looks abroad on the universe with the eye of a poet and with the breast of a glad and grateful worshipper. When he looks up to the starry firmament, his soul assimilates to the splendour and serenity which he contemplates. His lofty but bland spirit of devotion peculiarly reigns in the eighth and in the nineteenth psalms. But, above all, it expands itself in the 104th into a minute and richly diversified picture of the creation. Verse after verse in that psalm leads on the mind through the various objects of nature, as through a mighty landscape; and the atmosphere of the scene is coloured, not with a dim or mystic, but with a warm and clear light of religious feeling. He spreads his sympathies over the face of the world, and rejoices in the power and goodness of its protecting Deity. The impressions of that exquisite ode dilate the heart with a pleasure too instinctive and simple to be described."[1] Such also are the Song of Solomon, the Proverbs, Ecclesiastes, the Lamentations, and the Book of Job, with large portions of the prophetic books, and occasional passages even in the narrative books, such as the Song of Moses and Miriam, Jacob's dying prophecies to his sons, the triumphal chant of Deborah, Balak's involuntary blessing on the people whom he came to curse, and, above all, the exquisitely pathetic and beautiful lamentation of David over Saul and Jonathan. Amongst the Hebrew prophets, viewing their writings apart from their divine inspiration, and merely in the light of poetical compositions, the highest rank is universally ascribed to Isaiah; and that on account of the union of excellencies which his sacred poetry exhibits. Deeply pathetic in some portions, as in those where he paints the destruction which is about to fall upon Judah; awfully sublime in others, as where he describes the descent of the Assyrian king into the regions of hell, while all the dead monarchs of the earth rise up to greet him with reproaches; he rises with equal ease to themes of rapturous exultation, or spreads out in minute portraiture all the tranquil and soothing images of a coming millennium. "Joel," says Mr Campbell, "may be deemed to surpass him in continuity, and both Joel and Habakkuk are at moments more sublime. But their compositions are much shorter than his, and give us not the same conception of copious and unwearied inspiration. Isaiah's genius goes farther on an even wing, and burns longer with an unwavering fire. When he has merely to relate, his language has the utmost plainness; and his expositions are remarkably clear, considering the nature of oracular poetry. He unites the same simplicity with his rich and high visionary scenes, which are neither meagre like Jeremiah's, nor ambitiously overwrought and complex like Ezekiel's. A deliberate air, a divine self-possession, turns the very scorn and wrath of his spirit into movements of grace and beauty."

Jeremiah and Ezekiel belong to the declining period of Hebrew literature. They had fallen upon the evil days of their country, and the influence which its misfortunes and degradation produced on the mind, is peculiarly visible in the melancholy strains of Jeremiah. "His genius seems to bend, his voice to falter, under the burden of prophecy; and though sometimes pleasingly affecting, he generally prolongs the accents of grief to monotony, and seldom avoids tautology except where he abridges the works of other prophets." Ezekiel is the last great prophetic poet of the Hebrew line; and opinions have been divided as to the poetical rank to which he is entitled. Dr Lowth thinks that he is not excelled in sublimity even by Isaiah himself; Michaelis, on the contrary, that he displays more luxuriance in amplifying and decorating his subject than is consistent with true poetical fervour. Mr Campbell adopts the view of Michaelis, but adds, that the fancy of Ezekiel is daring and ingenious. Ingenious hardly appears to be the term applicable to the imagination of Ezekiel, which revels with peculiar pleasure in visions of a mystical, and, it must be admitted, somewhat confused sublimity. Some passages, however, are most powerfully impressive, such as the vision of the four cherubims in the first chapter, and the resurrection of the dry bones in the thirty-seventh, when there was "a noise and a shaking, and the bones came together, bone unto his bone;" and the prophet calls unto the wind, "Come from the four winds, O breath, and breathe upon these slain, that they may live; and they stood up on their feet, an exceeding great army."

But whilst the Hebrew poetry equals, and indeed far excels, that of any other nation in the sacred lyric, it is singularly defective in the other departments. The Song of Solomon, laying aside its spiritual meaning, may be admitted to be a fine specimen of the pastoral: but of dramatic and narrative poetry the Hebrews have left no specimens; for, though the book of Job has to a certain extent a dramatic form, it has clearly nothing of the essential qualities of the drama. This has been ascribed mainly to the theocratic nature of the Jewish constitution, in which the Levites or priesthood formed the sole and literary aristocracy; thus devoting poetry exclusively to religious themes. But, considering the ample field which the Jewish national religious history afforded, it is not easy to see why, if the genius of the people had inclined toward narrative or dramatic poetry, the Exodus, the wanderings in the desert, the wars carried on under the judges, and the many other striking events which gave interest to their annals, should not have been embodied in verse, as they were in prose, in the narrative books of the Old Testament.

But, though the poetry of the Hebrews is the first in the order of time, it cannot properly be regarded as the fountain-head of that literature, the course and connection of which we trace in an unbroken series of great works down to the present time.

The sacred poetry of the Hebrews, no doubt, impressed upon the literature of Christianity some strong and remarkable features; but it was from the fountain of classical literature that the genius of modern Europe first drew its inspiration. It is therefore to Greece that we must turn, as the head of that great family of literature with which we feel ourselves connected by relationship of thought and association.

Greek Poetry.

On turning from the poetry of the Hebrews to that of Greece, we are immediately struck with one distinctive feature, which, as applicable to the whole of its poetry, we may notice before adverting to the different departments into which it is subdivided, viz. the more palpable, material, and distinct character of all its conceptions and imagery. This immaterial, vague, and spiritual character of the Hebrew poetry, dwelling more on emotions of the mind than on actions, and on the invisible rather than the outward and visible, is unquestionably to be ascribed in a great measure to the predominance, in the national mind, of a pure and elevating religious creed. On the other hand, the Grecian mind, formed under the influence of a mythology which was in fact a mere deification of the material world, and which certainly exercised no strong influence save on the fancy, banished those themes and trains of thought which led beyond the visible diurnal sphere, and, concentrating its attention upon the present, gave to all its imagery a distinctness of outline, a simplicity and pellucid clearness in the thought, which, if less suited than the Hebrew to the excitement of the evidences of the sublime, was certainly in a corresponding degree favourable to the creation of beauty. The Hebrew poetry, therefore, is contemplative and subjective; the Grecian plastic and objective.

In an outline like the present, of the progress of poetry, it is needless to dwell upon the subject of the anti-homeric poets of Greece. That there were poets before Homer, we know; and this is really the extent of what is known on the subject. That the *art* of poetry had been cultivated to a considerable extent, that its principles had been subjected to reflection and experiment, when Homer lived, is as clear as internal evidence in any case can make it..

---

[1] Campbell's Lectures on Poetry, i.

Poetry improves only as painting and sculpture rise to perfection. "In sculpture," says Herder, "what a track must it have travelled over in passing from the figures on the chest of Cypselus to the decorations of the Propyleia and the Minerva of Phidias, or from the sculptures of Dædalus to the Olympic Jupiter. A like track was travelled by poetry in advancing from the rude lays in honour of gods and chiefs to the Homeric Epos." We know, indeed, that many of the minstrels before Homer had sung theogonies and cosmogonies, the adventures of Titans and heroes, of Hercules, Theseus, and the Argonauts; and in all probability the legends of the siege of Troy, and the return of the chiefs engaged in that enterprise, had formed the subject of many a ballad or rhapsody, ere a Homer arose to give them unity, proportion, and poetic life. All these have faded and been forgotten, for the tablet of human memory is narrow, and, to give room for the last and best, the older and ruder inscriptions must be erazed. Not one of these, accordingly, has descended to us in any authentic form; whilst the spuriousness of most of the Orphic poetry is unquestionable. Whether even an Orpheus ever existed, was doubted by Aristotle; and Herodotus distinctly states his belief, that the poets given out as older than Homer were in fact of more recent date.

We do not enter into the details of the question whether the works which bear the name of Homer were the productions of one man, and written in their present form at the period commonly ascribed to them, namely, nine hundred years before Christ, or whether they were originally the work of many rhapsodists, in portions separate and distinct, and afterwards woven together in a collected form about the time of Solon and Pisistratus. The question is, in fact, of less importance in reference to the history of poetry than might at first sight appear. For whatever view may be adopted, it is clear that the spirit, the tone, and the manners which are described in the separate lays, supposed to have been ultimately incorporated in one, are those of the earlier and not of the later period, and that the Iliad paints the Grecian mind and character as it appeared three or four hundred years before the time of Solon, and that from draughts made at the time. If so, the only way in which the adoption of the modern theory of Wolff affects the question is, that it deprives Homer of the merit of one grand general design, consistently followed out. It is certain, however, that whatever difficulties may attend the supposition of the Iliad and Odyssey being written by one man, in their present form, and at the early date ascribed to them, and preserved in the absence of writing by mere oral tradition, the difficulties on the other side are infinitely greater. To suppose that a set of scattered lays, composed by a number of unconnected minstrels, should ever have been made to cohere so smoothly and compactly, evincing such perfect unity of plot and purpose; that they should have been confined to so small a portion of the Trojan legendary history, and have given such prominence to a single Thessalian hero; seems a supposition far more startling than any that attends the belief that the Iliad is the work of a single author. "For inspiration is a solitary creative spirit; and it is not to knots and groups, or accidental fabricators, that she has ever intrusted those great conceptions in poetry or painting, or the fine arts, that have commanded the permanent homage of mankind." Many smaller additions, by other hands, in the same spirit and style, may have been afterwards superinduced upon the original work of Homer. (See the article HOMER.)

Epic poetry.

The two great poems of Homer are the first specimens of *The Epic*, or narrative poem. It is, in fact, from the Iliad in particular that our conceptions of an epic poem have been derived, and its canons deduced. What Homer has done has been consecrated as establishing inviolable rules to be observed by his successors. The epic is, upon the whole, the noblest form of poetry; that which demands the highest and most sustained power of imagination, combined with the simplest and purest taste. The power of tragedy is greater for the moment; for its presentations, assisted by action and visible form, are more vivid; but the epic, possessing a wider compass, and painting only by words to the eye of the mind, has a more diversified, enduring, and tranquil operation. Rapidity, strength of passion, vehement and animated dialogue, are the essential requisites of tragedy; a calm, sustained, progressive, and sober majesty the characteristic of the epic. "Of dramatic pieces," says Herder, "we remember sentences; the characters move before our eyes, we feel their emotions with them. But this emotion being stronger, is also briefer; it passes away. The epopee, with its more quiet working, with its proportions too vast for any stage to compass, fills the soul, and there abides." The other points noticed by Aristotle, "revolutions of fortune, recognitions, characters, passions," are common to both, as well as to fictitious composition in prose. Every romance written on any high principle is, in fact, a prose epic; the epopee in verse merely adds to the other sources of interest the charm of poetical diction, and of those elaborate ornaments of figures and similes, which, though stately and appropriate in verse, only produce a bombastic and ridiculous effect in the prose of Fenelon, or still more in that of Macpherson.

Essentials of the epic.

An epic, then, is the poetical development, in narrative, of some great and interesting event, or series of events, sufficiently separate from what goes before or follows, to possess the character of a whole; having, therefore, a clear and distinct beginning, middle, and end; an action simple at first, leading into a complication of plot, and terminating in a natural and soothing solution. These are its essentials; amongst its accidental features are the employment of supernatural agency as a medium either of heightening emotion or of conducting the plot; the introduction of episodes, of formal addresses, invocations, and similes; matters which have no essential connection with epic poetry, and the propriety of the introduction of which varies with the theme, the age, and the national associations of the poet.

How far suited to modern times.

To the confusion of these accidental qualities, many of which are certainly quite unsuited to the taste of modern times, with those essential features which must have an equal interest for all time, must be ascribed the numerous failures which in modern times have thrown a certain discredit and air of ridicule upon the epic poem; as well as the belief that appears to prevail, that the time for epic poetry is past. Unquestionably any epic now written which deals with fabulous mythologies or exploded superstitions, and employs in the nineteenth century the long elaborate speeches, the minutely touched similes, the formal enumeration of ships, and muster-rolls of regiments, which suited the primitive times of Homer, when description was new, will probably share the fate of Leonidas or the Epigoniad. But in the hands of a poet selecting a theme of sufficient natural and human interest, remote enough to allow play for the imagination, yet near enough to make us understand and sympathise with his actors, and treating it, not in a slavish spirit of imagination, but with the vigour and independence of original thought, we are persuaded that the epic would be found to have lost none of its power. It seems to be an entirely mistaken opinion, that the epic is only the production of an early and comparatively simple state of society, and therefore unlikely to harmonize with the more complex nature and critical taste of more advanced civilization. On the contrary, the Jerusalem of Tasso, the Paradise Lost of

Milton, and the Lusiad of Camoens, the only three modern epics which deserve the name, are the productions of what may be termed the golden age in point of taste in each country, and of individuals uniting to poetical inspiration all the stores which the widest reading and most sedulous cultivation of learning could supply.

The Homeric epics, and their characteristics.

The great powers of Homer are distinguished from all modern epics, by their wonderful air of truth, their broad clear portraiture of character, infinitely varied, and yet not antithetically contrasted; their perfect absence of all affectation, false sentiment, or exaggeration, either in character or sentiment; their calm and impartial spirit; their serenity, cheerfulness, and good sense. Such a union is indeed not to be expected in a modern state of society; after poetical description has already traced all the leading outlines both of moral and material nature, and when men, insensibly and unavoidably subjecting the influences from things without to a process of intellectual chemistry from within, and thus, connecting them with peculiar associations, cease to have either the power or the inclination of simply reflecting back on their verses, as in a mirror, the impressions of nature as they fall upon the mind. Neither, although the power of delineation existed, can it ever be expected that such materials for broad, simple, and effective painting can be found in modern times, when differences of character are veiled, if not in a great measure obliterated, by community of education and habits, or are converted into mere humours or peculiarities, to which the shades of distinction are too minute for any grand poetical effect.

Even the greatest of our modern epic poets, in painting the manners and the moral habitudes to which chivalry gave birth, laboured under the disadvantages of pourtraying feelings which, springing, as they had done, out of a visionary and unreal, because exaggerated, sentiment, had a tendency to run into caricature, and to give a monotonous and hyperbolical cast to their delineations of human character. The beings painted by Homer, who himself lived upon the outskirts of the heroic times of Greece, were in their features the men whom he saw around him; beings natural, open, and unsophisticated, both in their good and bad qualities: the manners simple, primitive, and homely, yet not without a touch of grave courtesy and refinement; the scenery which forms the foreground or background of his human groups as yet undepicted, the incidents through which they pass unhackneyed; all nature was before him where to choose: while the language which was to be employed as the medium of his art, neither debased by vulgar associations, nor diluted from its original freshness and strength by metaphysical refinements, which diminish its picturesqueness, in proportion as they render it more complex and philosophical, affected the mind with all the distinctness of sounds and colours, and stamped upon it an impression fresh and immediate, as from the signet of nature.

The power of invention displayed by Homer in his two great poems, in the conception of character, can only be fully appreciated when we recollect, that the germ or outline of almost every character which has since figured in epic poetry is to be found in the Iliad. Now, though the wonderful variety of his incidents, his battles, sieges, and storms, his nocturnal adventures, his combats of gods and men, and his scenes of enchantment, may have been in a considerable degree derived from his predecessors, and, in fact, the hereditary and traditional *properties* of the ballad minstrels of Greece, it is impossible to conceive that he could have derived much aid from this source in giving individuality and life to character. And yet, with the exception of characters under the influence of the passion of love, such as Dido, Armida, and Erminia, scarcely any substantial addition has been made to the picture gallery of Homer by later epic poets. His characters, in fact, have been like stereotypes, from which new impressions are constantly reproduced. Achilles, with his union of ferocity and gentleness, generosity and vindictive feeling, has been the model of all our mixed characters of passion since, and reappears in Turnus and Rinaldo; just as the kingly Agamemnon, with his grave dignity, has formed the archetype of those which represent the ascendency of reflection, and the moral power of sustained and tranquil grandeur, as in the Godfrey of Tasso's poem.

The Iliad.

The characters of the Iliad are naturally the more varied, because its subject was a great public event, and the actors were the congregated princes and heroes of Greece and Asia; the Odyssey is the poem of domestic life, the tale of the fortunes of a single hero, to whom all the other personages are purposely placed in subordination, but whose character, by this isolation, gains a degree of distinctness and natural truth absolutely unequalled in fiction, save in some of the creations of Shakspeare. The remarks of Mr Campbell on the characters of the Iliad are so just and beautiful, that we cannot deny ourselves the pleasure of quoting them.

"Achilles, in the centre, is of the order of spirits that electrify and command mankind. His alarming and sensitive being is the soul of the Iliad, and his very absence and repose are the causes of its disastrous action. He is unquestionably ferocious, but his quarrel is just; he is wronged, high minded, hating falsehood like the gates of hell, young, beautiful, and predestined to fall. Casual glimpses of his manners are also given, that interestingly soften our conception of him. He is the only hero of the Iliad who amuses himself with music and poetry. The deputies of the army find him in his tent playing on his lyre, and chanting heroic songs; and, though he knows their hateful errand, he receives them with a calm and manly benignity. Horace does him injustice when he calls him a disclaimer of laws, and inexorable; for he melts into tears at the prostrate gray hairs of Priam, the father of the slayer of his friend, though he had lately withstood all the eloquence of Nestor.

"It shows the security of Homer in his inspiration to have introduced such an opponent to Achilles as Hector. But when he leads us to Troy, he makes us Trojans in our affections, and almost seems to become so himself. Prodigal in sympathy with the events and agents which he conjures up, his imagination as tenderly conceives the lamentations of Hecuba, and the heart-sick swoon of Andromache, as it makes itself impetuously congenial with the vengeance of Achilles. Like nature, he is fruitful in creating characters, and, like her, impartial in distributing and intrusting virtues to contending parties. Conscious that Achilles could shine by his own light, he fears not to show us his image through tears for the fate of Hector. In delineating Hector by the eulogies of his weeping country and friends, the climax is exquisitely perfected by Helen. All others who had bewailed him, she says, were bound to him by reciprocal ties; but hers was the grief of gratitude for the undeserved and gratuitous kindness of his mighty heart. He had interposed when others had reproached her; he had soothed her when her tears flowed at their reproaches.

"Æneas creates a less ardent, though still respectable interest; and it is increased by a hint, which is thrown out with an air of minute historical probability, that Priam was jealous of his greatness, and that his virtues had been partially thrown into the shade. What expression in every figure of this mighty tablet! What diversity even between men incompetent to great actions; as between the abject coward and vulgar braggart Thersites, and the gay good-natured Paris, whose spirit, though sunk in luxury, still shows some traces of his noble breed! The stout heart and arm of Ajax stand him in lieu of all piety, craft, or sensibility; whilst Sarpedon, bleeding in warfare not his own, spends his last generous breath in exhorting the brave to rally the battle. Homer is above all artificial antithesis in the painting of character; but in describing natures remotely different, he could not avoid exhibiting contrasts; and that which is visible between Achilles and Ulysses is as perfect as heroic nature can afford.

“The youthful Diomed is, among the Greeks, next to Achilles, the apparent favourite of the poet: all spirit and lustre, his valour burns like ‘the unwearied fire that plays on his shield and crest.’ Like Achilles, he is insulted by Agamemnon, who charges him with cowardice on the eve of battle; but he is wise as well as warlike, and it is not till his actions have belied the imputation, that he retaliates upon his commander. When the Greeks have been worsted, and when Agamemnon proposes abandoning the siege, Diomed, the youngest of all the chiefs, rises in the council, and gives him a dignified rebuke. Agamemnon himself is not without the virtues of fraternal affection, and willingness to listen to able counsellors. He has also his day of distinction in the field. But his importance altogether is more royal than personal, and his faults are made conspicuous by his supremacy. Alternately presumptuous and despondent, he is the readiest to tax others with deficient courage, and the first himself to despair under public reverses. He is also unmerciful in victory. The cry for quarter is addressed to him in vain, and he makes two of the most atrocious refusals to spare that occur in the Iliad. It has been remarked, that Homer speaks as a friend to royal government; but still he describes it as too limited, or rather as too undefined, to be despotic; and the chiefs in the councils of the Iliad present us with a sort of Greek picture of Gothic feudalism. And if he shows respect for monarchy, he makes his kings no monopolists of virtue. In poetical justice, he seems to have thought it sufficient to give Agamemnon the diadem, and a few good qualities, as his share of importance in the poem, leaving brighter heroic endowments to chiefs subordinate in political power.

“Amidst these forms which the Iliad exhibits in the bloom or strength of heroism, the aged characters are no less happily distinguished. Nestor looks back on a life of greatness and wisdom:—he has no rival in venerable years; his powers have reached the last ripeness of experience, but they have also something of the mellow tint that precedes decay. He dwells on his own exploits with an egotism and fulness that could only be endured in the most ancient of men. Phœnix, the friend of Achilles, on the other hand, is also old, but his youth had been embittered by misery and vindictive passions; and when he comes to exhort the hero against excessive resentment, he confesses his early errors in a tone very different from the self-complacency of Nestor.

“Priam is neither very wise nor energetic; but his heart is warm with natural affections, and his woes and years sustain our reverence and solicitude. When the wail of the Trojans bursts from their walls, at the sight of Hector dragged in triumph by his conqueror, when the frantic father implores his friends to let him go forth and implore the pity of the destroyer, the struggle of his people to detain him, and the voice of his instinctive agony, surpass almost everything in the pathos of poetry, and affect us more like an event passing before our eyes, than a scene of fictitious calamity. Never was the contrast of weakness and strength more fearful, than when he throws himself at the feet of Achilles, whilst his feeble perspicacity makes us tremble at every moment, lest he should light up the inflammable temper of Achilles, fluctuating between wrath and compassion. Yet, hallowed by paternal sorrow, age and weakness prevail. The old man accomplishes his point, and the terrific victor condescends to the delicacy of even veiling Hector's corpse from his view.”

The Od sey.

The Odyssey, with certain common resemblances to the Iliad, is marked also by striking differences; so great, indeed, as to afford room for believing, not that it was the work of several hands, but that it may be the work of a different poet from the author of the Iliad. None of the gods and goddesses who play a part both in the Iliad and Odyssey appear the same in the latter poem as in the former. Jupiter, the representative of force or power, and the arbiter of all things in the Iliad, resigns the conduct of the hero to Minerva, the personification of wisdom. Menelaus, Helen, and Ulysses himself, leave a different impression on the mind. Manners and morals have changed. There is a perceptible advance in knowledge and the mechanical arts. There seems a decline in physical strength. The chivalrous spirit of the Iliad is exchanged for a more prudential and calculating one. Voyaging and wandering come in place of warfare. The qualities most valued are no longer the wild strength and energy of Achilles, but the self-possession, energy, forecast, invention, and eloquence of Ulysses. The agency of Magic, in room of a purely divine agency, a power of which we have no hint in the Iliad, finds a place. Wonders and prodigies are scattered with a profusion unknown to the Iliad. Many portions of the Odyssey have an air of resemblance to the Arabian Nights; and Sinbad would seem to have borrowed more than one of his adventures from Ulysses. It is not even difficult to perceive that the vocabulary and syntax of the language have in some measure altered. Each poem seems, as Herder remarks, to have its peculiar atmosphere, its sky, its panorama of objects in the upper, the middle, and the nether world.

Ulysses, the hero of the latter poem, is a conception more in harmony with ancient than modern views of heroism. Our ideas on the subject have been so strongly influenced by those notions of the point of honour introduced by chivalry, that we do not easily sympathize with a hero who, though not deficient in bravery, is always more ready to employ craft than courage, and only appeals to arms when artifice is found to be ineffectual. The character embodies, as Mr Coleridge observes, the idea of an accomplished man of the world, after the manner of ancient paganism; and it is therefore with some effort that we, whose ideal of such a personage is so different, interest ourselves in his fate. Yet he does make his way at last into our affections. His character grows upon us like the gradual influence of good sense. Human traits peep forth under the guise of impassive constancy and caution. His home-sick longings for Ithaca, his abandonment to the power of love under the influence of Circe, remind us of our common humanity. He bears his trials so firmly, he steers through difficulties with such tact and skill, and meets danger, when it must be met, with such self-reliance and courage, that he gradually acquires our admiration; and when we become more familiar with the kindly and warm affections which, after all, burn on in his breast beneath the crust of stoicism, he at last engages our sympathy and our love.

Hesiod.

The poems of Homer are at once the first and the last great specimens of heroic song in Grecian poetry; for it were out of place, in an outline like this, to allude to the middle school of the epic, while even the attempt to revive heroic poetry in the Alexandrian period only proved that its life and soul was extinct. Even in the Odyssey, as already mentioned, we perceive a decline of the enthusiastic and chivalrous spirit, a tendency towards the commercial and the peaceful. Imagination is gradually “fading into the light of common day.” This tendency appears, however, far more remarkable in the works of Homer's immediate successor, Hesiod. We say successor, because, although some authorities represent him as older than Homer, and Herodotus speaks of him as Homer's contemporary, the balance of evidence is clearly in favour of the superior antiquity of Homer. The precise date of his appearance, however, cannot be fixed with more precision than as having been between eight and nine hundred years before Christ. The works which bear his name consist of the Weeks and Days, the Theogony, and the Shield of Hercules, of which the latter is generally regarded as spurious. Looking to the subjects and character of his poems, which are of a domestic and peaceful character; to his style, which, though highly natural and simple, is, in the main, flat, level, and uninspired by high imagination; we should almost imagine that a full century must have elapsed between the Odyssey and the Weeks and Days. The time, adventures, battles, moving accidents by flood and field, and expeditions undertaken to recover some fair runaway "that enchants the world," seem to be for ever gone. In their stead we have an account how labour fell to the lot of man, the story of Pandora, our gradual degeneracy from the gold to the iron age, precepts of agriculture and commerce, moral and religious admonitions, which have much the air of trite proverbs and commonplaces of what deserves no better name than cunning and worldly wisdom; every thing, in short, indicates the triumph of the spirit of peace over that of war. The Theogony is in a somewhat more ambitious style; and, as a catalogue or muster-roll of the Grecian divinities, with a regular deduction of their genealogies, is curious. Unfortunately, however, its finest passage, the battle of the gods and Titans, a piece of genuine vigour and sublimity, appears so different from the style of Hesiod, that it would rather seem interpolated at a later time by some scholar, whose work has in this case very far surpassed his master's. On the whole, Quinctilian has criticised Hesiod with judgment and fairness. "Raro assurgit Hesiodus, magnaque pars ejus in nominibus est occupata; tamen utiles circa præcepta sententiæ lenitasque verborum et compositionis probabilis, daturque ei palma in illo medio genere dicendi."

ie Ho- ric mns.

The Homeric hymns, a series of compositions in praise of the gods, and probably of a date a little later than the age of Hesiod, seem to bridge over the passage from the epic and heroic poetry to the lyrical. The steps of the transition may even be in some measure traced, in the gradual ascendency acquired by the musical accompaniment which had from the first been employed in the recitation of the epic, but to which a greater prominence was given in the hymns, thus leading on to the decided influence of the lyre and pipe, and consequent accommodation both of the form and character of the poetry to that lyric mould in which it was thenceforward to be cast. Terpander himself composed the music for these Homeric rhapsodies; and Hesiod is said to have been denied admittance to the Pythian games because he could not accompany his verses on the harp. These hymns, strange, quaint, some almost comic; others, like that to Hermes (the finest of all), full of a wild and dancing gaiety; almost all treating the inhabitants of Olympus with a free and easy familiarity; abounding in rapid transitions, invocations, and reflections or sentiments of the writer; prepared the way for the more regular lyric, as it appeared in the strains of Archilochus (about 700 B. C.), to whom is assigned the distinction of being the father of the Grecian lyric.

e lyric try of ece.

The perfection of the Greek lyric had grown out of the intimate connection of poetry with music, fusing the finest results of both into a whole, which, charming the senses and the soul at once, hurried away the listener with an irresistible sweep of enthusiasm. Every thing in the circumstances of Greece contributed to its rapid development and unfailing effect. A spirit of gaiety and social enjoyment was the national characteristic, heightened by the influence of a delightful climate, and by a religion whose airy and fantastic character interposed no gloomy reflection to check the enjoyment of the present. The public and family festivals, sacrifices, games, and poetical contests, assembling multitudes together, exciting the spirit of rivalry, and gratifying the poet as it were with a foretaste of his poetical immortality, the high honours and distinctions everywhere paid to song, rapidly advanced the art to perfection. It is probable, that if the whole mass of the Greek lyric poetry could now be recovered, not only would Horace, Catullus, and the Latin lyric writers, be unquestionably shorn of many of their finest passages, but, in all probability, we should be presented with the noblest and most varied collection that the world has ever produced. For if the light luxurious Bacchanalian spirit of the time be imaged in the graceful trifling of Anacreon's festive songs, we know how the deeper and more gloomy sentiments of a genuine passion were embodied in the burning lines of Sappho; the ardour of military enthusiasm in him who sang his verses to the Spartan fife, Tyrtæus; the inspiring themes of patriotism in "Alcæus, fancy drest, singing the sword in myrtles dressed;" the touching tenderness of maternal affection in the Danae of Simonides, weeping over her child in her frail and sea-beaten prison; and, above all, the loftiest strains of religious fervour, the praises of demigods and heroes, all the pride, pomp, and circumstance of human existence, in the odes of the greatest master of the Grecian lyre, Pindar. But, unfortunately, of the works of the nine who are enumerated by the ancients as forming the constellation of the lyric writers, and embracing the period from the death of Hesiod down to the great era of the Persian war, viz. Pindar, Bacchylides, Sappho, Anacreon, Stesichorus, Simonides, Ibycus, Alcæus, and Alcman, some have completely perished, and of others only the most trifling fragments remain. Anacreon and Pindar are the only two of which we possess any considerable specimens.

Sappho.

Judging from the few fragments we possess of Sappho, the loss of her works is particularly to be deplored; for she appears to have possessed not merely that wild fire and hurry of passion which predominate in her celebrated ode (with which every one is familiar in the version of Phillips), but a tenderness of heart, a power of presenting imagery in a line or a word, not surpassed by any of the ancient writers, and justly entitling her to the lofty title of the Tenth Muse, bestowed upon her by antiquity. How exquisite, for instance, is the fragment preserved by Demetrius Phalereus,

> 'Εσπερε παντα φερεις
> φερεις οἰνον, φερεις αἰγα
> φερεις ματερι παιδα.

Thus expanded, yet scarcely improved, by Lord Byron:—

> O Hesperus, thou bringest all good things
> Home to the weary, to the hungry cheer,
> To the young bird the parent's brooding wings,
> The welcome stall to the o'erlaboured steer;
> Whate'er of peace about our hearthstone clings,
> Whate'er our household gods protect of dear,
> Are gathered round us by thy look of rest;
> Thou bringst the child too to the mother's breast.

Pindar.

Pindar unquestionably occupied the highest place among the Greek lyrists; and though it is certain that we are in possession of only a small part of his works, for he appears to have written on every variety of theme, enough remains to satisfy us that the judgment of antiquity, which raised him to the lyric throne, was well founded. Forty-five triumphal lays, in honour of the victors in the public games, have descended to us, and the character and peculiar merits of these have been described with such eloquence, and at the same time critical justice, by Sir Daniel Sandford, in his able sketch of the rise and progress of literature, that we quote the passage in preference to any remarks of our own.

"The most careless reader of these odes must be struck by the excessive admiration of wealth, magnificence, and every species of greatness, to which we have alluded as a characteristic of Pindar's mind. Splendour was the passion of his soul; splendour of achievement, splendour of renown, splendour of station and outward circumstances. His very pride seems to have suggested to him that nothing but splendour was worthy of his muse. His genius, to use a figure of his own, was the eagle of Jove, that would not be severed from the sceptre and the god. These aristocratic predilections, this enthusiastic attachment to munificent monarchs and chiefs of ancient fame, were in perfect unison with the whole tenor of his destiny; born as he was in the midst of the Pythian festival, living surrounded by shows of solemn pomp, and dying, as he had lived, in the full blaze of public ceremony, in the centre of a theatre, and while rapt in those emotions of rejoicing sympathy which such scenes were sure to awaken in his bosom. To those, however, who may deem apology requisite for the indulgence of so stately a temper, it may be urged in behalf of Pindar, that, as in the case of many remarkable poets, the abstract feeling of veneration was predominant in his mental constitution, and that it was called forth not merely by rank and opulence among mankind, but even more powerfully by the contemplation of the divine attributes. Hence that glow of piety which shines so brightly in his odes, sometimes breaking out in expressions of the deepest awe, or in sublime pictures of deity, and sometimes assuming an aspect of moral beauty, adding force and lustre to the lessons of wisdom. The latter modification of religious feeling has given birth to some of the noblest passages in the poetry of Pindar. He was well aware that emotion does not exclude sentiment; that the ethics of the heart are not less sound than those of the brain; and that nature is often hurried, in moments of excitement, into the innermost shrines of truth. But he knew likewise, that the philosophy of such moments is prompt and peremptory; oracular, not syllogistic; and this knowledge has secured him from frequently offending against the genuine character of lyric song by lengthened trains of moral reflection."

When the lyric poetry of Greece had reached its perfection in Pindar, its drama rose into shape and grandeur in the tragedies of Æschylus. But for the history of the progress and decline of the Greek drama, tragic and comic, the reader is referred to the article DRAMA in this work.

Decline of Greek poetry. Alexandrian school.

Little remains to be said of the declining portion of Greek poetry. General corruption, introduced by luxury, and the evil principles of the sophists; loss of liberty, when all the powers of Greece had yielded to the sway of Alexander; the introduction of a tumid oriental taste into eloquence and composition in general; such are the features which mark the period from the rise of Alexander the Great to the extinction of the poetical literature of Greece. After the death of Alexander, indeed, a strong effort was made by the Ptolemies to render Alexandria the rival of Athens, and to assemble about their court poets, orators, and men of science. In the latter point only their efforts were successful. Science continued to flourish, and long after Greece had ceased to produce any great works in the fine arts, we find geometrical invention carried to a height by Euclid, whilst the wonder-working science of Archimedes struck the Romans at the siege of Syracuse with terror and astonishment. But eloquence remained, as before, hollow and pompous, whilst poetry was in a great measure wasted in the vain attempt to give life and interest to the abstractions of science. This was the period of the learned or didactic poetry. Mythology, astronomy, botany, were the favourite subjects to which the art of the poet was devoted. One attempt, however, to revive the epic taste is visible in the elegant Argonautics of Apollonius Rhodius. He cannot indeed be regarded as an epic poet, for he wants fire and originality; but he is a graceful compiler of traditions, the effect of which he heightens by occasional touches of tenderness.

Pastoral. Theocritus.

The most interesting, however, and by far the most original, of the works of the decline of Greek poetry, are the Idylls of Theocritus (270 B. C.). One is at first surprised to find the appearance of the bucolic or pastoral poetry, so late in comparison with the heroic, the lyrical, and the dramatic. As it seems to paint a primitive period of human nature, we are led to think that it would be one of the first forms in which poetry would appear. The truth is, however, that it has generally made its appearance, and has always been most popular, in ages of great social refinement, when excess of luxury in the life of cities drives the mind back upon the supposed simplicity of rural life and its occupations. Such was the case with the Greek Idylls of Theocritus, with the Bucolics of Virgil; with the pastoral dramas of Tasso, Guarini, and Bonarelli; and with the pastorals of Pope and Phillips. They are all the growth of a period of great literary refinement. Frederick Schlegel observes justly, however, that there is an essential error in isolating pastoral poetry, as is generally done, and viewing the country life abstracted from its due situation in that picture of the world and of human life which it is the province of poetry to unfold. "Let us reflect for a moment on those passages in the heroic poems of antiquity, or in the chivalric romances of the moderns, which afford us glimpses of the simplicity and repose of rural manners. Their simplicity appears still more innocent, and their repose still more peaceful, from the situation in which they are placed in the midst of the guilty tumult of wars, and the fierce passions of heroes. Here everything appears in its true and natural connexion, and the poetry is as varied as the world and the men which it professes to represent." It is certain that this treatment of the rural life as a department of life, by narrowing within the most confined limits the materials of the poet, is the cause of that monotony which is generally found to pervade pastoral poetry. Nothing, in fact, becomes more wearisome than the repetition of Arcadian descriptions of the golden age,

> Lactis uberes
> Cantare rivos atque truncis
> Lapsa cavis iterare mella.

But this fault is more prominent amongst the modern, particularly the Italian pastoral writings, than in Theocritus, who has in general painted his shepherds and peasants with a natural and manly simplicity, approaching even, as it seems to modern ideas, to coarseness. His Idylls, as indeed the name implies, are little poetical pictures or representations in miniature, sometimes of mythological subjects, at other times of matters of common life, but almost always amatory in their purpose and termination. With Theocritus may be classed, though far inferior to him in vigour, the "showy Bion and the delicate Moschus," the last names of any note which precede that period of exhaustion, when, the days of high imagination and great works being over, those of mere cleverness and neatness of execution, of slender trifles, epigrams, and anthologies, commenced.

LATIN POETRY. Its rise.

But as the genius of one nation, yielding to the force of circumstances, declines, nature seems to provide a principle of compensation in the development of that of another. The course of literature and poetry appears to resemble an arctic summer, in which the sun scarcely dips in one quarter of the horizon before he re-appears in another. While the creative energies of Greece either sink into barrenness or expand into a rank and unwholesome luxuriance, as her morals are corrupted, and her liberties impaired and at last extinguished, we perceive in the Italian peninsula the rise of a national character and a literature, destined, alike in arts and arms, in polity or in literature, to give laws to the world.

This not till centuries after the existence of Rome.

Yet Italy, free and independent as she was, and animated by a consciousness of national pride and growing power, exhibits during the first five centuries of her history (735 B. C. to 253 B. C.) a mere blank, so far as poetry is concerned. That she *may* have possessed legendary ballads founded on those various mythic or semi-historical traditions which were afterwards interwoven by Livy into his history of Rome, is not improbable; but of the nature of these we know nothing, of their existence at all we have no certain traces; and nothing can be more fanciful than the extent to which Niebuhr, Schlegel, and other German writers have carried their conjectures on this subject.

ivius Anronicus.

In fact, we know nothing of Roman poetry prior to the introduction of the Greek language and literature, through the conquest of Tarentum (272 B. C.) and Magna Græcia; soon after which the rude attempts of a Greek slave, Livius Andronicus, to translate the Odyssey of Homer into Latin (240 B. C.), first gave the victors some idea of the poetical treasures of that nation, to which, though victors in the field of warfare, the Romans felt their inferiority in the more peaceful domain of literature. His preferring the wilder and more homely of Homer's poems to his more imposing, elaborate, and dignified performance, only showed that he rightly apprehended the tendencies of an infant taste. Children as they were in poetry, the power of the marvellous had attractions for the Romans, which that of simple yet heroic truth would probably not have possessed. The efforts of Andronicus to diffuse a taste for Greek literature did not stop here; for he was the translator also of several specimens both of the tragic and the comic drama of Greece.

nnius.

He was succeeded by a Roman poet of original though coarse and unequal genius, Ennius (239 B. C.). Yet, with strong originality of mind, he was a worshipper of Greek literature; and his influence on his successors is probably owing in a higher degree to what he transplanted from the soil of Greece, than what he reared from the independent stores of his mind. He attempted by turns, epic, tragic, satiric, epigrammatic, didactic, and even acrostic poetry. He versified the Roman Historical Chronicles, a poem of which few specimens survive, but these calculated to excite much regret that a work, executed with so much force and feeling in parts, should have been irrecoverably consigned to oblivion. His vigorous and forcible style, with all its rudeness, conceits, and ridiculous jingles, appears in its better parts to have possessed great charms for the best judges of diction at an after period; for we find that Virgil, Lucretius, and Ovid, and particularly the first, have availed themselves most liberally, not only of the ideas, but of the precise expressions, and frequently whole lines, of Ennius;[1] while Horace, who seems to have had a warm feeling of the poetical fire that lay under the rude crust of the verses of Ennius, after citing two of his lines, says that the "disjecta membra poetæ would appear visible," however their arrangement might be transposed; a result which, he fairly admits, would not be the case with regard either to the satirical works of Lucilius or his own.

lautus d Tence.

Neither in Ennius, however, nor in his dramatic successors, Plautus (died 184 B. C.) or Terence (born 195, died 159 B. C.), do we meet with much that is truly national. In all we are in fact perusing Greek compositions in Roman forms; for the plays of Plautus and Terence present to us, not the aspect of Roman life, but the state of Greek society, pretty much as it had appeared in the days of Menander. In the former we perceive more vigour, more variety, broader humour, but at the same time more coarseness; in the latter a limited invention, and characters reducing themselves to a few limited classes, generally an over-indulgent father, a profligate son, a rapacious mistress, and a knavish slave; to which Plautus is fond of adding some Bobadil or parasite, by way of relief. Yet in Terence's case we perceive the traces of genius, notwithstanding the close imitation by which he is fettered. His characters have a truthful air, his dialogue is always free from affectation, and sometimes touching and tender in the highest degree. In fact, a few of his best passages in this style are models of apparently artless and yet consummately artful and beautiful expression.

Lucretius.

Two other individuals of distinguished genius precede what is called the Augustan period of Roman poetry, Lucretius and Catullus; the one the most distinguished of the Roman didactic poets, the other unequalled in the short and tender lyric. Lucretius contended with an absolutely unmanageable subject; one which, from its unimaginative character, from the dreary details, psychological, meteorological, geological, which it necessitated, the inherent feeling of discomfort which it leaves behind, and the irreligious character of the opinions which it involves, necessarily interposed the most formidable difficulties in the way of the poet, which it is no disgrace even to the most distinguished genius, and such Lucretius possessed, not to have entirely overcome. It is, in fact, the highest proof of the ability and genuine inspiration of Lucretius, that he has infused a poetical vitality even into the dry bones of that philosophical mummy which he was attempting to animate; that he has treated with a feeling of poetical enthusiasm the coldest and most heartless of all creeds, the Epicurean; so that the very strains which he has employed in combating the belief of the immortality of the soul, bear upon their face the stamp of immortality. "In inspiration and in sublimity," says Frederick Schlegel, "he is the first of Roman poets; as a painter and worshipper of nature, he is the first of all the poets of antiquity whose writings have come down to us."

Catullus.

In Catullus the Epicurean theory, which wears a majestic aspect in Lucretius, appears in a less dignified but more probable form. *Carpe diem* is the motto which might be inscribed over all his compositions; yet with this enjoyment of the present mingles not absolutely a melancholy, but a pensive feeling, which gives a peculiar interest to them all. For compositions of a higher mood and more extended plan, Catullus apparently had as little ability as inclination; his taste was Grecian, and formed in the school of Alexandria; slight performances, epigrams, elegies, little lyric effusions expressive of individual feelings, like the charming lines to Sirmio, or the lament for the sparrow, and polished with the most exquisite felicity of diction, were the subjects to which his talents were devoted. There is, in fact, every reason to believe that his more ambitious performances, such as the Epithalamium of Peleus and Thetis, and the Atys, were simply editions in a Latin form of Greek originals.

The poets hitherto mentioned belong to the period of the republic; in their successors, the poets of the Augustan period, we perceive a considerable change both of spirit and expression. Under the calm but firm sway of Augustus, which had reduced all the contending parties under one powerful dominion, and conferred upon the country the blessings of peace, the art of poetry was peculiarly cultivated and patronized. And it is at this period that the Roman poetry first displays in its fullest extent that feature which Frederick Schlegel considers its truly national and original trait, namely, that exaltation of Rome and of the Roman character; that feeling of the unrivalled energies, the rapid growth and ever-increasing dominion of their country, which formed, to the imagination of the poet at least, an ample compensation for the loss of that liberty which, since the commencement of the troubles of the Gracchi, or the contests of Sylla and Marius, had been little better than a political phantom, or a party watchword with no real meaning.

Virgil.

The great representatives of this Augustan period of poetry are Virgil and Horace. No two poets could be more dissimilar in the direction of their tastes, and yet it would be difficult to say to whom the palm of greater genius ought justly to be assigned. Even in his Pastorals, though an early work, the leading qualities of Virgil's mind, his exquisite taste and fine sensibility, are apparent, though they can hardly be considered in any other light than as graceful adaptations, and, it may be safely added, *improvements*, of the subjects and manner of Theocritus. In these he was painting from a painting; he was copying a Greek landscape in the colouring of the Latin tongue. But in his Georgics he drew from his own observation of Italian nature; and, bringing the native excellencies and qualities of his mind to bear upon imagery and events and associations which nature and experience had dictated, presenting us with delicious landscapes varied by all the natural occupations of the Italian agricultural life, gilded by sunshine, clouded by storm, or darkened and disturbed by tempests; combining these in the most dexterous manner with striking allusions to well-known events and catastrophes of Roman history, such as the prodigies which portend the death of Cæsar, or with old mythological traditions; and making the driest details of husbandry, such as the grafting of trees or the breeding of bees, prolific of imagery or of fable consecrated by early associations; the result is one of the most original and at the same time delightful poems which exists.

---

[1] Dunlop, History of Roman Literature, vol. i. p. 21.

The Æneid was a great, but, it must be admitted, unsuccessful attempt to do that for Rome and the Roman people which Homer had done for Greece, namely, to give the Romans a great national poem. No one felt this failure more than Virgil. His reluctance to give publicity to the Æneid is well known. He could only be prevailed upon to read to Augustus the first, second, fourth, and sixth books. Several causes may be obviously assigned for its want of success. 1*st*, Not only did Virgil, from the intense admiration he felt for Homer, copy in many respects his characters and design; but he endeavoured to combine the distinct and almost incompatible characters of the Iliad and the Odyssey, the grand and warlike character of the former with the wandering and adventurous character of the latter poem. 2*d*, Although the notion of grafting the adventures of Æneas upon the origin of the Roman nation, was in itself a happy one; and the mythological traditions connected with it might have been brought to bear with much effect upon the subject; Virgil committed the great error from which Tasso has also suffered, of making an epic poem a mere instrument of political flattery, by identifying the character of his hero with that of Augustus. By depriving himself of the open and untrammelled field which the traditional character of Æneas presented, and making that character a mere portrait, *en beau*, of the cold-blooded, calculating, and critical emperor, he lost at once all hold over the sympathies of the reader in the fortunes of his hero, a cardinal point in all poems that pretend to the character of epic. 3*d*, Nay, he even enlisted those sympathies against him; for, as Voltaire, who is seldom wrong in what may be called the logic of poetry, observes, he represents him as a mere adventurer, who in the first place is guilty of the most shameless want of feeling in regard to Dido, whose sole object is to acquire a settlement in Italy; who, in breaking off the match of Turnus with Lavinia, is instigated, not by passion, but by policy; and who would in all probability have most willingly surrendered the Latian princess to his brave and generous though cruel rival, if *he* would have resigned the kingdom of Old Latinus to a Trojan stranger, and taken Lavinia, like Cordelia, without a dower.

Only one substantial addition has been made by Virgil to the characters of Homer, and for that character he may have received some hints from the Ariadne of Catullus; but it must be admitted to be one of the most deeply interesting in poetic fiction, we mean that of Dido. The great night-picture of the sack of Troy, and the episode of Dido, are indeed the finest things in the Æneid. In the character of the Carthaginian princess, we perceive the infinite advance which the delineation of the passion of love has made since the time of Homer. Virgil has begun to comprehend that feeling, with the world of emotions to which it gives birth. And if he has not painted it with all that purity and depth which was imparted to it by Christianity, he has exhibited its leading traits with a warmth and sensibility which make all the other classical delineations of passion both cold and lifeless beside that of Dido.

Horace.

Horace exhibits the singular specimen of a poet borrowing half his thoughts from the lyric writers of Greece, and making his odes a mosaic formed from the gems of other countries as well as his own, and yet imparting to the combination a high degree of unity, and a decided originality of character. Calm wisdom, shrewd penetrating observation of life, a sober enthusiasm, and most refined taste, are the qualities which most distinguish him, imparting to all his compositions extreme point, terseness, and occasionally, in themes of a higher cast, particularly those connected with the elder worthies of Rome, or the lofty position she then occupied in the eye of the world, a stately and solemn grandeur. This admirable balance of mind which distinguishes Horace, and informs all his writings with such pregnant good sense, renders him a peculiar favourite in a country like our own, whose national character is marked by not a few of those features that distinguished the mind of the poet. Hence his odes are more read and quoted, particularly by men of business and practical sagacity, than the works of any of the classic poets.

But the merits of Horace, though most conspicuous as a lyric poet, are great also as a satirist. Lucilius had indeed made the first approach to the regular form of Roman satire; but his rude and harsh effusions can no more be compared to the polished and graceful productions of Horace, than the rugged verses of Donne can be compared with the satires and epistles of Pope. In Horace all follies and lighter vices of the day (for he seemed to think satire scarcely a fit weapon when directed against the darker vices) are touched on in a strain of the most urbane ridicule, which insinuates reproof. As compared with those either of Lucilius who preceded, or of Persius and Juvenal who succeeded him, the tone of the Horatian satire is light and playful. It has been correctly observed, that these satires filled up for Roman literature exactly the department which in our times is occupied by the stage. For as the plays of Plautus and Terence truly represented Greek and not Roman manners, it was in the light form of satire that all those humorous follies and oddities of Roman society, which properly fall within the range of the comic, were displayed and exposed.

The elegiac poets.

The elegiac poets of this period, Tibullus and Propertius, wrote with purity and good taste; the former with more of tenderness, the latter with more of force and mental vigour. But in the extravagant luxuriance and frequent conceits of Ovid, we perceive the commencement of that decline of poetry, which, relieved only by the manly vigour of Juvenal's satires, goes on in rapidly-increasing progression to the extinction of the Roman empire. For the amatory and elegiac poems of Ovid little can be said; they want heart and passion as much as delicacy or propriety of sentiment. But the praise of a teeming fancy cannot be denied to him; he is a mine from which thoughts and expressions may be dug without end; and his Metamorphoses, as a graceful exposition of the finest mythological tales of antiquity, will always retain their interest for modern times.

Juvenal

We pass over the so-called tragedies of Seneca, the works of a mere school rhetorician; and the satires of Persius, obscure and rugged, though not without a masculine energy. But the name of Juvenal must be mentioned as the last great poetical name that illustrates this period of decline.

In the finer portions of his satires, for it must be admitted they contain a good deal that is level and prosaic enough, he displays the highest talents for this species of poetry; the strength of his language, the fire of his invective, correspond with the gigantic character of the vices which he exposes. But a certain air of exaggeration mingles with and alloys the effect of his censures; we are led to think of the doubtful character of his own life, and to question the title of the moralist to raise the scourge which he applies with such severity to others. A tinge, in short, of that rhetorical and formal character which his mind appears to have contracted in the schools of declamation attaches to his poetry, and leaves an impression of hollowness and insincerity upon the mind.

Lucan.

Lucan's Pharsalia, it must be recollected, was a comparatively boyish effort; but it seems plain, from the character of his mind, that he wanted the highest of the poetical faculties, imagination. He uttered bold and striking thoughts occasionally in the happiest words. No poems afford finer specimens of single lines for quotation than Lucan. But the whole is destitute of poetical warmth; it blazes only with a phosphoric fire. Quinctillian has, in fact, hit with admirable tact the character of Lucan's mind in the remark, "Si dicam quod sentio, oratoribus magis quam poetis annumerandus."

We shall not here touch upon the remaining writers who feebly kept alive the vestal fire of poetry up to the period of the overthrow of the Roman empire of the west; Statius, Claudian, or Ausonius. Even the introduction of Christianity, much as it did towards improving morality, not only among its votaries, but amongst the Pagan nations themselves, could not re-animate to new life the worn-out and enervated frame of literature. That could only be effected by sweeping away entirely the old landmarks, making a new heaven and a new earth, creating new associations in all the ideas of men, giving them new hopes, aspirations, and pursuits, and thus restoring that elastic principle of moral and mental vigour, of faith and enthusiastic feeling, out of which all high poetry must spring. From the rude but warlike and uncorrupted nations of the North was to come that influence which was to give a new aspect to society; at first, like the descent of a deluge, sweeping the remains of cultivation before it, but ultimately depositing and carrying deep into the bosom of the soil the elements of a reviving and healthy fertility.

POETRY OF MODERN EUROPE.

From the fall of the Roman empire of the West, about the close of the fifth century after Christianity, to the appearance of the first great poet of modern Europe, Dante, an interval of seven dreary centuries elapses, a period characterized in popular language by the epithet of the dark ages. During this period the chaos resulting from the overthrow of the old Pagan constitution in religion, government, laws, and social institutions, was gradually settling into shape; the new religion was incorporating itself with and imparting a new form to social life; new laws superseding the subtile and complex jurisprudence of Rome, new languages growing out of its ruins. During the greater part of the period to which we have alluded, literature, in any high sense of the word, did not exist; but the materials of new literatures were accumulating, and the spirit which was to give them breath and vitality, when language should be sufficiently settled for the purpose, was developing itself, though manifesting itself in other fields and departments than that of poetry. When poetry re-appeared in the thirteenth century, the influence of the intermediate changes which the human mind had undergone became visible in certain marked traits, separating by the broadest distinctive lines the character of the modern European from the ancient classical poetry. A few of these, as applicable to all the modern literatures of Europe, though with differences in degree, may be indicated before proceeding to any notice of these separate literatures.

1. The first and most important is the influence of the Christian religion on the productions of the imagination.

The Pagan religions were mere religions of the fancy; they were nothing but the poetry of humanity. They dealt only with the palpable and the material; and by the combination of the finest features of the actual, they produced an ideal which each moulded to his own fancy. The conceptions of the infinite and the immaterial they avoided. The solemn and the mournful found no place in their thoughts, or, if such ideas did intrude, they were made use of as arguments for present enjoyment. Let us eat and drink, seems the moral of paganism; let us eat and drink, for tomorrow we die.

From this materialism of the ancient mythology, and its purely imaginative character, the results were, 1*st*, great clearness in all its conceptions and its expressions, that clearness which is imparted by the absence of all that is not palpable to sense; 2*d*, a light and cheerful tone, the natural product of that mental indifference, and absence of serious reflection, which the disbelief, or as least doubt of immortality, would produce; 3*d*, the feeling of *beauty* as the object aimed at and accomplished, and the vital principle of all the classical creations.

Very different were the character and the influence of Christianity. This was a revelation, not a creation of the fancy. It spoke to the heart, to the hopes and fears of men, not merely to their imaginations. The outlines of the Christian theology were communicated in a fixed and settled form, with which fancy could not deal at will, or mould them in accordance with its notions of beauty. It excluded at once that plastic power which had formed the excellence of Greek art and literature, and banished mere *beauty* as the aim of the poet, or the principle of modern inspiration.

To the clearness, the sunny lightness of touch, the cheerful levity of tone, which distinguish the classic poetry, it was equally unfavourable. It made the mind familiar with the ideas of infinity and eternity; it accustomed it to abstract conceptions beyond the pale of sense, or the scope of distinct expression; it forced upon its consideration the immaterial and the invisible, as constantly as the Pagan theology had confined the attention of its votaries to the visible and the actual. The Pagan clearness of portraiture, and smiling lightness of tone, were incompatible with the description of regions and states of being, sights and sounds, which eye had not seen, nor ear heard, and which it had not entered into the mind of man to conceive. The Christian poet, before whom, instead of a natural and visible Olympus and Acheron, there stretched out in dim but awful vision the conception of heaven and hell, encompassed by an eternity on this side and on that,—a conception impressed by the sense of moral responsibility, and of eternal punishment or happiness, and animated by a principle of faith based upon things not seen,—could not but carry into the literature which was the expression of his thoughts, and hopes, and fears, some shadow of that solemnity and mystery with which human life was now surrounded. He left this narrow spot of earth, already in the possession of his predecessors, to open up the new and undiscovered country of the abstract and the invisible; and the principle of poetical inspiration which they sought in beauty, he found in *grandeur* and *sublimity*. Hence earnestness and profundity are the means of effect in the literature of Christianity; and elevation rather than beauty may be said to be the aim of the higher poetry of the moderns.

2. The superstitions which grew out of the corruptions of Christianity, and which assumed a systematic form after the crusades had opened to Europe a communication with the East; the belief in spectres, fairies, witchcrafts, and the di-

rect interposition of evil spirits in the affairs of men; gave a different character to the modern literature of Europe. It is true, that in the Canidia of Horace, the Erichtho of Lucan, the Thessalian scenes of enchantment in the Golden Ass of Apuleius, and occasionally in other passages of the classical writers, we have allusions to popular superstitions somewhat analogous to our own; but it is equally plain that these are not matters of serious belief, but of poetical embellishment. They could not, in fact, cohere with any consistency with the framework of the antique materialism, though they might be combined with a religion which assumed the existence of powers unknown to human sense, and of a principle of evil, which, with limited powers, was permitted to oppose the principle of good. These conceptions of immaterial beings distinct from men, but influencing their actions, assumed a reality and appearance of probability, which soon rendered the belief in their existence one of strong practical influence upon society, and of course upon literature. Hence the gloomy and superstitious character impressed upon many of the earlier productions of all nations; and which, during the fifteenth, sixteenth, and seventeenth centuries, manifested itself in such fearful action in the atrocities of the trials and executions for witchcraft.

3. Whilst the Pagan mythology affected only the imagination, Christianity appealed to the conscience, and was calculated to operate practically upon conduct. We see, accordingly, in the history of the middle ages, that religion was not, as it becomes in after ages, a mere profession, often assumed from habit, but a principle of faith, of conviction, and of serious action. We see, through this invisible but powerful agency, a spiritual throne established at Rome, to which, weak and insignificant as it appeared in physical and economical resources, the most powerful monarchs in Europe were content to bow with implicit obedience. During the middle ages, the possession of the keys of St Peter was found a more effectual instrument of supremacy than the temporal sword. We perceive the clergy looked upon as a superior race; their persons and possessions considered as sacred; the rudest and boldest nobles of the time trembling at the thought of their anathemas, courting absolution at their hands, soliciting dispensations, founding monasteries and cathedrals, undertaking penances, pilgrimages, and crusades; and we see them often, in the midst of the fierce career of warfare, as if struck by some sudden inward but irresistible impression, throwing down the sword, exchanging the helmet for the cowl, and wearing out, as is told of our own Guy of Warwick, the evening of a stormy life in the peaceful cell of the hermit. There was in all this much of error, much of impure feeling and doubtful character; but there was also much of truth, much of earnestness; and hence faith and devotion are as visibly stamped upon the literature of the middle ages, as they unquestionably were influential upon its life.

4. Apart from the influence of religion, although not unconnected with it, there were other social changes which had strongly affected the course of feeling and opinion, and could not fail to render themselves visible in literature as soon as it began to assume a regular form. The most important of these was the institution of chivalry, growing out of, and affording an imperfect remedy for, the defects and evils of feudalism; an attempt, in fact, to create a species of police or constabulary, founded upon those principles of generosity and honour which were frequently found associated in the human mind with cruelty or licentiousness, during those stormy days of feudal dominion.

It was not, however, on its warlike and serious side that chivalry exhibited any very novel features; for, as far as regarded merely its spirit of adventure, numerous parallels might be found in ancient story to the exploits of its votaries. The feats of Theseus with the Minotaur, the story of Perseus's deliverance of Andromeda, the Argonautic expedition of Jason in search of the golden fleece, the more celebrated expedition against Troy, all closely resemble the exploits which chivalry prescribed to the members of its order. The true point of view in which chivalry gave a new direction to the opinions of the age, and a new impulse to literature, was in the altered position which it gave to women. It is certain, that before chivalry was known, nay, before Christianity was introduced, a peculiar reverence for women had been shown by the Gothic nations. Tacitus, in his treatise on the manners of the Germans, adverts to this as one of their characteristic features. "Inesse iis etiam *sanctum aliquid* et providum putant." The introduction of Christianity ratified and consecrated this feeling of respect. It made woman the equal and companion, not the slave, of man. But chivalry went a step farther. It reversed the relations in which the sexes had stood during the classical times, and exalted, in theory at least, the softer sex above the stronger and the more warlike. As the best means of arming the helpless against the powerful, it surrounded them with an angelic atmosphere of sacredness, and converted love into adoration, respect into religion. Here, too, there was something affected, but much more that was genuine. This feeling, exaggerated as it seems to us, did unquestionably influence in a high degree the opinions of the age, their tastes, their modes of expression. Its effect upon modern literature has been most remarkable. It has rendered the principle of romantic love almost the mainspring of modern poetry, and of imaginative composition in general. It forms almost the sole subject of the poems of the Troubadours, the minstrels of the south of France, Spain, and Italy, with whose compositions the history of modern poetry properly commences. Dante, the father of the Italian language and poetry, finds the source of the inspiration which dictates his sonnets and canzoni, and at last the *Divina Commedia* itself, in this species of romantic adoration for a deceased mistress. Petrarch's poetry, and his deification of Laura, are one and the same thing. The lyric poets of the fifteenth and sixteenth centuries of Italy seem to have scarcely conceived that any other course than that of imitating Dante and Petrarch in this chivalrous Platonism was open to them. The principle of romantic love is carried by Pulci, Boiardo, and Ariosto to an excess which communicates to it an air of the ludicrous; a reproach, however, from which it is again redeemed by the serious and enthusiastic Jerusalem of Tasso. When in modern times the attempt was made to revive tragedy, it proved totally unsuccessful, until this principle was admitted into the drama to give it warmth and life. Of that species of composition which in its proper sense is peculiar to the moderns, viz. the novel and romance, it forms, as we all know, the moving power. In short, it influences, more or less, every department in which the imagination has exerted itself with success since the revival of literature.

5. Another point in the social institutions of the time, which affects in a considerable degree the spirit of the literature of the European nations in the outset, is the relation of feudal vassalage, the degraded condition of the mass of the people, and the subdivision of the state into so many separate baronies, within each of which its feudal lord exercised supreme authority. This subdivision annihilates that inspiration of *patriotism*, or attachment to country or state, which is very visible in the Roman literature, and more faintly in the Greek, and introduces in its stead the principle of *loyalty* or implicit obedience to the individual superior to whom fortune had given the right of disposing of the destinies of his vassal. Submission to authority under all circumstances, without remonstrance, is represented as the highest of virtues; and a violation of this principle cannot be palliated by any exhibition of courage or self-devotion. A fine illustration of this principle in the moral code

of the feudal times occurs in Schiller's fine ballad of the Fight with the Dragon, founded on a story given as authentic by Vertot, in his History of the Knights of Malta. Rhodes was laid waste by a monstrous serpent, which has already destroyed not a few of the knights of St John, who had been rash enough to engage in combat with it. The grand-master, accordingly, had strictly prohibited any of the order from engaging in the apparently hopeless attempt. One young knight, unable to witness with patience the spectacle of the misery and distress daily caused by the ravages of the monster, ventured to despise the prohibition, and, by dint of art and valour combined, delivers the island from its persecutor. He was conducted in triumph to the hall, where the knights were met in council. The grand-master received him in gloomy silence, reminded him that *obedience* under the Christian creed was the first of virtues, and banished him from the island. The knight, conscious of his error, bowed in silence, divested himself of his knightly mantle, kissed the hand of the master, and was about to go. The stern superior was softened; he called him back, and, presenting him again with his sword and mantle, informed him that his prompt submission and penitence has restored him to the rank which his disobedience had forfeited.

6. One other feature is strikingly characteristic of the earlier literature of Europe, although good taste at a later period has pretty well weeded out its traces, viz. the singular and incongruous mixture of science with poetry. The literary men of the time were learned men, familiar with theology and with the writings of the ancients, and delighted with the abstractions and refinements of a mystical theology and a scholastic logic; and that which interested them in reality, they unconsciously incorporated with their poetry. This tendency tinges the whole Italian poetry, from Dante to Ariosto. Petrarch, even while singing of love, cannot allow the subject to pass without some learned and complimentary allusions to Aristotle. The Spanish lyric poetry of Boscan, Garcilaso, and their successors, is a sort of versified Platonism. The verses of Ronsard, and the other worthies composing that poetical constellation which arrogated to itself the name of the Pleiades, are so full of learned allusions as to be absolutely unintelligible; and the influence of this somewhat pedantic exhibition of ancient literature is undeniable even in our own Milton.

Poetry during the middle ages.

Having premised these remarks on some of the characteristic features of distinction which separate the religious, reflective, warlike, and mystic poetry of modern Europe, from the airy, graceful, and transparent spirit of the classical, we may observe, that although, as we mentioned, nearly seven centuries elapsed before the appearance of any poet of permanent European reputation, poetry was not entirely idle during the intervening period; but, on the contrary, towards its close at least, in a state of high activity and fertility of production. Scarcely, indeed, had the different languages of Europe begun to arrange themselves into form, before poetry in a rude form made its appearance. Perhaps in Germany the cradle of the modern poetry of Europe may most probably be found. By the time of Charlemagne, it is certain that country contained a vast mass of legendary poetry, which was carefully collected, committed to writing by the directions of the emperor, with a view to preservation, but of which scarcely a traditional fragment now remains. Earlier than the time of Charlemagne (A. D. 740 to 814), in all probability, were the lays of the Nibelungen and the Heldenbuch composed, though they have descended to us only in the altered form given to them when recast by Henry of Afterdingen. The former carries back its scenes to the days of Attila the Hun; and in truthful simplicity and vividness of painting, its homely and nervous verses are even yet worthy of admiration. A fund of bold and rich invention is, in like manner, displayed in the Sagas of Scandinavia, the mythology of which, at a later date, came to exert a strong influence over the poetry of Europe.

Provençal.

The Provençal language, the first-born of European tongues, in which Thebaut afterwards sung, and Cœur de Lion expressed his complaints in prison, we find moulded into form about the close of the ninth century. The Provençals had undoubtedly borrowed many things besides rhyme from the Arabian literature of the Peninsula, for an oriental spirit is visible in many of their compositions, and much of their imagery. But, on the other hand, they added much from their independent stores; they widely extended the domain of poetry, gave it spirit as well as refinement; they even rendered it, as Villemain observes, a substitute for the liberty of the press; while their forms of versification, canzoni, sonnets, sestine, madrigals, &c. soon became the patterns adopted by all the southern languages of Europe. Their compositions, introduced into Germany through the Hohenstauffen emperors, instantly communicated a marked impulse to German poetry: the numerous band of the Minnesingers of the twelfth and thirteenth centuries are, in fact, the Provençals of Germany.

Trouveres.

In the north of France, again, arises, during the same period, the literature of the Trouveres; a literature of satires and legends, and tales of knavery, licentious gallantry and adventure, destined afterwards strongly to influence the direction of the genius of Boccacio, and his successors the Italian novelists, and to furnish the amplest materials for later writers of fiction. Nor during this creative period were fictions of a higher cast wanting.

Three cycles of legendary romance.

Three leading cycles of romance may indeed be pointed out, which owe their origin to this period. The first consists of the legends of Gothic, Frankish, and Burgundian heroes, during the times of the great northern emigrations, of which the Nibelungen and the Heldenbuch are the depositories; legends breathing a purely northern spirit, and generally having some foundation in history: the second, those which embody the traditions as to Charlemagne's wars against the Saracens, the achievements of his court of Paladins, and the "dolorosa rotta" at Roscesvalles, where he is represented as perishing with all his peerage. In these Charlemagne is strangely represented, not as a most warlike and energetic monarch, but rather in the garb of a lazy and luxurious eastern sultan; a perversion of historical truth which, Frederick Schlegel thinks, must be accounted for by the poems which refer to the emperor having been chiefly written by Normans, who drew their notions of Charlemagne from some of those faineant monarchs of their own days, whom they saw in possession of his throne. It is certain, at all events, that the legends connected with Charlemagne soon became largely interwoven with incidents of a comic cast, and with a mass of absurd and fantastic machinery. The third class of romantic traditions then first embodied in poetry are those relating to the fabulous Arthur, "begirt with British and Armoric knights;" by far the most interesting of which is the celebrated legend of a pathetic and elegiac character, which bears the name of Tristan or Tristram. "Among all the great and epic poems of love and chivalry in the middle ages," says Frederick Schlegel, "the first place is given by all nations to Tristram; but that we may not be fatigued with uniformity of fiction, the airy and lively legend of Launcelot is placed by the side of its more grave and elegiac representations." He traces also in these legends of Arthur and the Round Table a double purpose; an allegorical character, viz. an attempt to shadow forth the ideal of a spiritual and Christian knighthood, imparting to them in general a higher character than to the corresponding traditions of Charlemagne.

The Monkish hymns.

One other class of the compositions of the middle ages may be alluded to, their monkish hymns, written in Latin, that is to say, the bastard Latin of the period, and generally in rhyme. They cannot indeed be praised for their novelty of thought, or high imagination; but their earnestness of purpose, whether in describing ideas of terror or pity, and which was the expression of one belief and one heart pervading many nations, give them a considerable hold over the mind. No one can be insensible to the awful grandeur of the *Dies iræ, dies illa,* which Roscommon, who translated it into English, is said to have died repeating; or the simple pathos of the *Stabat mater dolorosa,* which, even divested of the charms of Pergolesi's music, speaks to the heart. Of nearly equal beauty are the *Jam mœsta quiesce querela* of Prudentius; and the *Ave Maris Stella,* being an invocation to the Virgin, which may still be traced in the songs of the boatmen of the Mediterranean. The forcible impression made by these simple sacred hymns on the mind of Dante is obvious, from the manner in which lines or portions of lines from them, are here and there woven into the *terza rima* of his great poem.

It cannot therefore be said that the middle ages were an unpoetical period. On the contrary, there was then a very general diffusion of poetic feeling. But the poetry to which it gave rise was not marked by any of those works of excellence rising conspicuously above the rest, which attract attention to the names of the authors. Its productions are chiefly anonymous; its poets have died and made no sign. A great genius was still wanting to form an epoch in the annals of poetry; but that genius was found in Dante, about a century after the Tuscan dialect had assumed a predominance over the other dialects of Italy.

ITALIAN POETRY.
Dante.

The Divine Comedy of Dante (born 1265, died 1321) is the first work of distinguished and original genius which graces the literature of modern Europe; and it is in many respects a most striking and remarkable production. It is not, as the name would import, a drama; as little does it resemble an epic poem; it is an allegorical pilgrimage through heaven, hell, and paradise, which the poet has peopled with human shapes, human passions and crimes. He has made his poem an instrument through which he vents his political loves and hatreds, his vast and undigested learning, his scholastic acuteness, his mystical philosophy, his reverence for the ancients, his sympathy with the spirit of freedom, the enterprise, the enthusiasm of the moderns. It resembles, in fact, the Homeric poems in its encyclopædiac character. The poet stands, as it were, on an isthmus, from which he can cast back his glances across the tumultuous and still heaving chaos of the middle ages, into the serener regions of the past, and forward into a futurity of which he foresees and foretells the coming glories. Many, no doubt, had been the allegorical compositions which went before him; the Roman de la Rose, indeed, still survives, in the translation of which Chaucer wasted so much of his earlier powers; but all have been thrown into shade, and it may be said effaced, by the grasp, magnificence, and sombre power, combined with deep human feeling, of the great allegorical pageant of Dante. For in this last quality, quite as much as in the attributes of sublimity and grandeur, which are universally conceded to him, lies the secret of that perennial charm of freshness which still gives interest to the *Divina Commedia.* Amidst the darkest scenes of infernal punishment some soothing objects or images are constantly introduced to lighten our pilgrimage, and flowers are made to spring up beneath our feet, as if to freshen the path "over the burning marle." His wearisome metaphysics have long ceased to please; his mystic raptures, his pictures of the celestial occupations of the saints, appear almost ludicrous; his demons and his Satan grotesque rather than impressive: but the deep pathos of the story of Francesca of Rimini; the thrilling scenes in the town of Hunger; the few simple lines which tell the story of Madonna della Pia, imbibing a slow but certain death among the swamps of the Maremma, to which she is consigned by a jealous husband; the sweet apostrophe to evening, and the fireside recollections which the sound of the vesper-bell brings along with it: these and such episodes are the passages which linger in the memories of all, and give to the poem of Dante its main hold over the heart.

The imagination, on the other hand, is singularly roused by the scenes of torture and bliss through which we are led, the burning tombs, and cities alive with flame, and valleys of the shadow of death, where serpents torture their victims, and the ever-deepening descent through the circles of hell, contrasted with the cheering light which begins to break upon us in the ascending circles of purgatory, and the refulgence of the visions which greet the wanderer on his entrance into paradise, when he exchanges the guidance of Virgil for that of Beatrice.

Distinct as the imagery in the foreground is, the prospect fades away on all sides into the illimitable, and the imagination has full room to expand itself in the sphere of the mysterious and indefinite. Dante's poem may, indeed, be well compared to that "wild and hoary wood" in which he describes himself as losing his way in the outset, with here and there a path cut through the trees, where the sunshine pours in and shows spots of verdure or still waters, but backed on all sides by dusky labyrinths, inhabited by beasts of prey, into the gloom of which the eye can hardly pierce, and the immemorial stillness of which the sound of human footsteps has never broken.

The style of Dante's poem is scarcely less remarkable than its spirit. Obscure and unyielding, as might be expected, in some parts, it has, nevertheless, a picturesqueness without parallel in modern literature. It makes every object palpable or sensible; flashing images upon the mind with the rapidity and the splendour of lightning. "They are," says Ugo Foscolo, "the bold and prominent figures of an alto-relievo, which, it seems, we might almost touch, and of which the imagination readily supplies those parts that are hidden from the view." It fixed the Italian language, so that at this moment it remains less changed since the time of Dante than any other European tongue.

Petrarch.

As Dante is the head of the Italian allegorical poetry, so Petrarch may be regarded as the founder of the lyrical; borrowing indeed his manner, and not a little of his matter also, from the Provençals, but by a refined taste acquired from the deepest study of the classic poetry, and a sensibility, the liveliness of which was quickened by a real passion, investing their strains with a character of tenderness and perfect finish, which really appear to confer on them a different character. The monotony disappears of which we are conscious in reading the compositions of the Troubadours and Minnesingers, "qui toujours d'un même ton semblent salmodier;" and a wonderful variety of emotions are seen to arise out of a theme which, in their hands, had appeared limited and barren. No one has ever drawn a finer poetical ideal of female loveliness, purity, and worth, than Petrarch has done in Laura. "Every lover," says Herder, "will find *his* Laura in that of Petrarch; he will find his own heart, with all its weakness, and that beneficent influence which the female character in its purity can erect over the disposition of the youth and the man." The verbal subtilties and plays on words which disfigure many of the lyrics of Petrarch no doubt detract from their effect, and excite surprise that one whose taste was in general so pure should have given admittance to such conceits; but, like the puns and equivoques of Shakspeare's time, they were part of the fashion of the day. Petrarch found them imbedded, as it were, in the Provençal poetry from which he drew, and he yielded, like Shakspeare, to the evil influence of the time. Upon the whole, however, the services rendered by him as an Italian poet (for we need not here allude to his great and most beneficial influence on the taste of Europe, by his exertions on behalf of classical literature) have been very great; he sensibly added to the polish, grace, and pliancy, of the Italian tongue; and of the Platonic poetry of love, a love existing rather as a lambent glow than as a flame, and living on as a sentiment after it has ceased to be a passion, Petrarch still remains the purest and the most charming representative. (See the article PETRARCH.)

he Pe-
archists.

It is a remarkable fact, that though the genius of Dante was unquestionably far more masculine, original, and imposing than that of Petrarch, the former left no successors, while Petrarch turned for nearly two centuries the whole current of poetry into the direction of the amatory lyric. Dante was found to be unapproachable; within the circle he had formed, none durst walk but he; but the Platonism of Petrarch, and the apparent simplicity and brevity of the medium through which his tranquil and gentle inspiration was conveyed, appear to have tempted every one into imitation of his lyrics. Hence, until the fifteenth century in Italy was well advanced, its poetry consisted of little else than imitations of Petrarch. But, in truth, though this was not perceived, all the finer essence of Petrarch's poetical character was nearly as incommunicable as that of Dante; and accordingly we find, among the latter Petrarchists, that much of the delicacy and truth of Petrarch, that *feeling* which gives a tempered warmth to his expressions, and calms without chilling the heart, disappears. The raptures of love, and that struggle of passion and reason which so constantly recurs in Petrarch's poetry, are pitched in an exaggerated and falsetto key; the conceits grow more numerous as the feeling grows less intense and real; till at last, of all which their great original had produced, little is found transplanted into their imitations, save the indestructible harmony of the versification.

The fifteenth century, which followed the death of Petrarch, is fruitful in learned men, in grammarians and philosophers, but barren in poetry. The excessive cultivation of classical literature, and the admiration excited by its great models, created a feeling of distaste for Italian composition. Traces, no doubt, of a teeming fancy appear in the unfinished stanze of Politian; and the rustic and carnivalesque songs, both of the great Lorenzo and of Machiavelli, have a merit independently of the interest attached to their authorship. Machiavelli's comedy of the Mandagola has been pronounced by a competent judge to be amongst the best specimens of the comic which the Italians possess. But till the rise of that branch of poetry which may be regarded as the peculiarly national poetry of Italy, namely, the serio-comic romance of chivalry, nothing of a marked or original character appears. We turn, therefore, at once to the dawn of that school in the rough poem of Pulci.

rio-co-
c ro-
nce of
ivalry.

There seems little doubt that feudalism, with that attendant spirit of chivalry which was born of its union with religion, never obtained any great influence in Italy. Petrarch even speaks of the warlike fictions of romance with dislike and contempt; and indeed, from the earliest periods, we can perceive the traces of a commercial much more than a military spirit; inclining the nation, in the adoption of foreign models, to turn with far greater interest to the gay, lively, and licentious tales of the Trouveres, or the dreamy reveries of the Provençal poets, than to those tales of chivalry, the "romans de longue haleine," which formed the study and the delight of the rest of Europe.

Before the period, too, when the Italians first thought of resorting to the fictions of chivalry as the materials of poetry, the feeling of chivalry itself was generally on the decline throughout Europe, and its high-flown sentiments and extravagances in action were beginning to be looked upon as a superannuated and exploded fashion. Hence the consciousness of a certain air of ridicule attaching itself to themes of this kind must from the first have been present to the minds of the Italian poets; and accordingly the chief puzzle connected with the work of Pulci, the Morgante Maggiore, is, whether the work be of a serious nature, or an elaborate jest; or whether, as seems more probable, it be not a jumble of both.

All the Italian poets who have adopted these fabulous themes of chivalry seem, in fact, to have perceived that, in their own country at least, the taste for romance, if it ever existed, had gone by, and that a serious poem, in the style of the prose romances of chivalry, would have met merely with ridicule or neglect. Their aim, therefore, seems to have been to avail themselves merely of the fictions and machinery of romance, as affording a new source of poetical embellishment; to address no higher feeling than the principle of curiosity aroused by complicated adventure; and to anticipate, by a tone of levity, and a gaiety approaching to the comic, that ridicule with which they felt that the spirit of chivalry had begun to be associated. They wrote "as if they mocked themselves, that could be moved to *sigh* at any thing." This aim is visible in them all; they differ only in the degree of art, taste, and genius with which the result at which they aimed has been accompanied.

Pulci.

In the rude poem of Luigi Pulci (born 1431, died 1487), there is no harmony whatever between the extremes of the tragic and comic. The poet appears to be in one page sincerely devout; in the next he seems a profligate and scoffer. The broadest farce in the adventures of the good-natured but stupid giant Morgante, alternates with the elevated and the pathetic in the really chivalrous enthusiasm of the battle of Roncesvalles and the death of Orlando; the dreariest platitudes are succeeded by occasional outbreakings of devotional enthusiasm or fine sentiment. The effect of the whole is disjointed and painful, and such as to excite our surprise that the accomplished companion and favourite of the great Lorenzo should have produced a work so enigmatical and unsatisfactory.

Boiardo.

With more invention and greater variety than Pulci (for in the construction of plots, and in sketching the outline of characters, Boiardo left little for Ariosto to perform), and with far less of that disposition to caricature in which Pulci unconsciously indulges, the *Orlando Innamorato* of Matteo Maria Boiardo (1430 to 1494) still wants that airy grace and ease of movement, that unconscious flow, like the marvellous tale of an Arabian improvisatore, without which this species of poem,—a "chartered libertine," in as far as regards the ordinary canons of criticism,—can have no permanent success. In Boiardo's hands it moves laboriously and stiffly; his verse wants harmony; his style wants pruning, polishing, and lightening. This, together with the infusion into the poem of a most peculiar species of grave humour, was the service afterwards performed for Boiardo by Berni, with such perfect success, indeed, that the *rifaccimento* has superseded and almost obliterated the recollection of the original.

Ariosto.

It remained, however, for Ariosto (1474–1533) to hit the happy medium between the *poco meno* and *poco piu;* to blend the tragic and comic in the proper proportions suited to the serio-comic epic; to give life and natural movement to the mere machines of his predecessors; to throw over his recitals an air of simplicity and *bonhommie,* which gives probability to the wildest marvels; and to invest the whole airy tissue of romance, with a style, the peculiar charm of which, though most clearly felt, appears almost indescribable; so clear, so popular and translucent, as to charm the most uneducated; so correct and classical as to satisfy the most critical taste. To compare Ariosto to Tasso as a poet of feeling, is to compare objects absolutely disparate, and unsuited to comparison. Probably the native cheerfulness and easy temper of his mind was not consistent with strong emotion; but it is equally clear, that the expression of strong emotion was inconsistent with his plan. To have grafted the deep and serious interests and passions of men upon so gossamer a groundwork as that which he has adopted, would have been like building an edifice of marble upon the unsubstantial basis of a summer cloud. In the department he assigned to himself he has employed the most appropriate instruments with corresponding success. After Homer, he has been, on the whole, the favourite poet of Europe. Above sixty editions of the Orlando were published in the course of the sixteenth century alone. "The Orlando Furioso," says Mr Hallam, in summing up a most just and discriminating criticism of Ariosto, in his Introduction to the Literature of Europe, "as a single great poem, has been very rarely surpassed in the living records of poetry. Ariosto must yield to three, and only three, of his predecessors. He has not the force, simplicity, and truth to nature, of Homer, the exquisite style and sustained majesty of Virgil, nor the originality and boldness of Dante. The most obvious parallel is Ovid, whose Metamorphoses, however, are far excelled by the Orlando Furioso, not in fertility of invention, or variety of images and sentiments, but in purity of taste, in grace of language, and harmony of versification."

The incongruous elements of devotion and ribaldry, caricature and tragic emotion, which had been left unblended by Pulci, which Boiardo partly rejected and partly harmonized, had received from the pen of Ariosto the last graces of which such a poem was susceptible. In him there is even a gentle pathos combined with a sort of enthusiasm of valour, which gives sincerity and elevation to the fantastic. But the serious and brooding fancy of his successor Tasso (born 1544, died 1595) could not be contented to sing, like Ariosto, "le donne, i cavalier, l'arme, gli amori," in the same light, and at times half-mocking strain. He determined to present the serious side of the romantic epic, as Ariosto had done the comic. Whether the dull "Gazette in verse," by Trissino, the Italia Liberata, in any way suggested to him the idea of a historical subject, we know not. Certain it is, however, that his earnestness of purpose, his deep and at last morbid sensibilities, impelled him to the selection of a theme where reality should give steadiness and human interest to the creations of imagination; and where the spirit of the Christian religion should be the moving principle, instead of a phantasm which played round the head rather than touched the heart. This theme he sought and successfully found in the delivery of the Holy Sepulchre by the crusaders; an event more interesting to Christianity than had been the Trojan expedition to the assembled princes of Asia; and satisfying that essential condition of a good epic, that its action, whatever its importance, shall be one springing from enthusiastic feeling rather than political motives. His poem was written while the European monarchs still flattered themselves with the hope of regaining the lost conquests of Godfrey in the Holy Land, and the glorious exploits at Malta, at Rhodes, at the Goletta, and Lepanto, showed the strength of the feeling that still prevailed "against the general enemy, Ottoman;" and dealing as it did with a topic of religious interest, placed among scenes hallowed by the most affecting recollections, and presenting the finest natural features for the pencil of the poet; admitting, from the remoteness of the period to which it related, and the faith which then prevailed, the introduction of a fabulous agency, contrasting with the impressive machinery which the Christian religion afforded, it is difficult to conceive a theme uniting more features of interest, or affording a richer or more picturesque groundwork for an epic poem.

Tasso has conceived his plan in the spirit of antiquity, and in the grand and enlarged style of the classic epic; but he has executed it in the spirit of the middle ages; and perhaps the point in which Tasso has been more completely successful, is the skill with which the spirit of a religious chivalry is breathed into the classic framework; and all the incidents which he liberally borrows from Homer or Virgil, are made to harmonize with that prevailing tone of devotion, valour, and tenderness, which is spread like an atmosphere of purity over the Jerusalem Delivered.

The e
sodes.

Whilst the general plan of the Jerusalem, perhaps, bears too close a resemblance to that of Homer, in the retirement of Rinaldo, like Achilles, from the army, which is made the nodus of the poem, the singular beauty of its episodes has been always felt and admitted. In fact, it is by the episodes that we chiefly remember the poem. Tasso has thrown the whole tenderness of his soul into such passages as those where he describes Sofronia and Olindo at the stake, the "pastoral melancholy" of Erminia's residence with the shepherds, or Clorinda perishing by the hand of him who would willingly have died to save her. The turn of his mind, in fact, was fully more towards the lyrical than the epic, and, in passages like these, the lyrical tendency breaks forth with peculiar force and flow.

Chara

In his characters Tasso has not made any very substantial addition to the picture gallery of the ancients, though even in this respect he is superior to Ariosto, who in most cases contents himself with a few general types without distinctive traits. Tasso's male characters, with one exception, that of Tancred, are judicious adaptations of Homer's outlines of character to other times, manners, and religious creeds. Tancred, however, is an original conception; perhaps the more striking that its outline was drawn in some measure from within; for in Tancred, the brave, visionary, melancholy Tancred, the victim of a hopeless passion, we probably see a dim reflection of the poet himself.

The same broad line of distinction which divides Ariosto and Tasso as to the conception of their subjects, may be traced in the whole details of their execution. Ariosto is throughout a painter. It is with external things that he chiefly deals; with colour, arrangement, form, and grouping, rather than with their internal spirit. But Tasso cannot paint this objectively. Every image, every feeling, as it passes through his mind, receives the stamp of his own peculiar habits of thought, and issues forth impressed with the image and superscription of his own tender and loving soul.

Pastor
and pas
ral dra

Though Tasso is best known by his great epic, his Aminta deserves notice as the finest of those pastoral dramas which were so common in Italy in the sixteenth century and the commencement of the seventeenth. It was not indeed the earliest, for the Sagrifizio of Agostino Beccari (1510–1590) had preceded it. And even Beccari's work had grown out of those pastorals, frequently in dialogue, of which the fifteenth century was so fruitful, and of which the Arcadia of Sannazzaro (1458–1530) affords the finest example. Tasso's, however, of all the Italian pastoral dramas, is the most inspired by the spirit of poetry. The Pastor Fido of Guarini (1537–1612) certainly has the advantage of a far more stirring plot; it rouses more curiosity and attention, but it wants the charm, the truly Arcadian repose, which Tasso has spread over his Aminta. Here also, as in his Tancred, the feelings of the poet gave vivacity and truth to the poem; for it is not difficult to see, that under the disguise of Amyntas, and in the form of allusions to the joys and sufferings of the pastoral life, or invectives against that influence of rank and honour by which the natural feelings of the heart are suppressed, the lover of Leonora is pleading his own cause, or his own apology.

For an account of the Italian drama, which took its rise in the Sophonisba of Trissino (born 1478, died 1550), the reader is again referred to the article Drama in this work.

Bernes
poetry.

One species of poetry, which is almost peculiar to Italy, distinguishes or rather disgraces this period, viz. that mass of poems entitled Capitoli, &c. which obtained the name of Bernesque from the poet who first set the example of these specimens of reckless and indecent drollery, Francesco Berni (died about 1543). His quiet, grave humour, the host of ludicrous associations which he conjures up, and frequent felicities of expression, at first render even his ribaldry amusing; but when similar themes were taken up and hunted down by Molza, Casa, Firenzuola, and their followers, it became oppressive and revolting in the highest degree.

We now approach the period of decline in Italian poetry. The sixteenth century had been its golden period: in the seventeenth we drop at once into the age of brass, or the age of tinsel. Chiabrera (born 1552, died 1637) indeed exhibits lyric fire, and, by discarding the hackneyed and outworn form of the Italian versification of the Provençal school, and approximating to the metres of the ancients, gave a character of originality to his odes. Yet, granting the boldness of his imagery, and a certain fervour and enthusiasm, which raise his lyric poetry above the slumbrous and monotonous beauty of most of his predecessors who were of the school of Petrarch, it is yet impossible to subscribe to the excessive eulogiums bestowed upon him by Tiraboschi, who almost seems to think he had combined in Italian the graces of Anacreon with the majesty of Pindar. More impressive, more affecting, though occasionally, and particularly in his sonnets, more deformed by the conceits and exaggerations which give an evil distinction to the poets of this period, whom the Italians have branded with the title of Seicentisti, are the lyrics of the senator Filicaja (born 1642, died 1707), whose religious canzoni, particularly the noble triumphal hymn on the deliverance of Vienna from the Turks by John Sobieski, are amongst the finest specimens of this class of poetry of which Italy has to boast. In his sonnets he is less pure and less natural; even his famous sonnet on Italy is, in its second quatrain, disfigured by one of the poorest and coldest of conceits. One other name must be mentioned, as preserving a pure and classic taste amidst the general corruption which, under the influence of Marini, was now pervading and perverting the whole spirit of Italian poetry. We refer to Fulvio Testi (1593–1646), the Italian Horace, as he has been called, a title certainly quite unmerited, so far as regards the power or brilliancy of his imagination, but not inappropriate, if limited to the purity and terseness of his style. The greater corrupter of this declining period of Italian literature is the once famous Marini (born 1569, died 1625), the author of the Adone, a poem which is an absolute chaos of brilliant antitheses and exaggerated language, plays of wit and ingenious imagery, but heaped together without the slightest direction of any governing judgment, and producing a tiresome and chilling, instead of an exciting effect. In his own days his writings were differently estimated. For a time, indeed, his popularity in his own country was boundless, and his influence on the literature of other countries, particularly that of Spain, as powerful as it was mischievous. But good sense and good taste shortly resumed their sway, and Rousseau, if one may judge from the frequent quotations from Marini in his Heloise, would almost appear to be the last person of any literary distinction who was familiar with the once celebrated and now completely forgotten Adone.

In comic poetry, however, the seventeenth century was more successful. To this period belongs the Secchia Rapita of Tassoni (1565–1635), the first specimen of that style which was afterwards carried to perfection in the Lutrin and the Rape of the Lock. The imitations of Tassoni need not be mentioned. Instead of improving on his model, they degraded and vulgarized it.

Excepting in the drama, which was distinguished by the great and strongly contrasted genius of Metastasio and Alfieri, the eighteenth century in Italy can boast of little in poetry. Some graceful fables by Pignotti, imitations of Pope by Parini, and of Gray and Young by Pindemonte, redeem it from the charge of utter barrenness, but cannot entitle it to the praise of originality. Nor, with the exception of Manzoni, has the nineteenth century produced any poem which can justly be said to have attained a European reputation.

SPANISH POETRY.

Of all the languages formed from the ruins of the Latin, the Spanish approaches the nearest to the Italian. The spirit of the two literatures differs extremely; but so closely do the words resemble each other, that translations have been executed by Spaniards from the Italian, as in the case of Jauregui's translation of Tasso's Aminta, where even whole lines are found to correspond with the original. The language, as it now exists, is the dialect of Castille, polished and purified, the Catalonian or Limousin having long ceased to be the language of poetry.

Its oriental character.

One feature peculiarly marks the whole of the Spanish poetry with a character unknown to that of the rest of Europe, viz. the strong traces of orientalism which it exhibits, a tendency to the pompous and the exaggerated, and a strange compound of strong passion, combining with a great wantonness and luxuriance of fancy. More or less this feature is to be traced through all the changes which its poetry has undergone; subdued, no doubt, and kept down by the good taste of such men as Garcilaso or Cervantes, but re-appearing in the *estilo culto* of Calderon, and reaching its height in the ludicrous extravagancies of the Spanish Marini, Gongora. Considering, indeed, the intimate connection which subsisted between Spain and Arabia from the eighth down to the close of the fourteenth century, a connection which, though one of hostility in the field, appeared to have admitted of many of the ties of friendship and mutual respect, and the natural admiration which the brilliant poetry of Arabia was likely to exercise over the minds of a ruder people, the Asiatic character of the Spanish poetical genius appears exactly what, under such relations, might have been expected.

Chronicle of the Cid.

The earliest monument of the Spanish poetry is the old Chronicle of the Cid, a cycle of romantic legends, founded upon the exploits and misfortunes of that Don Rodrigo Laynez who, after exalting the glory of the Spanish arms under Ferdinand king of Castille, and his son Don Sancho, was treated with such ingratitude by Alfonso VI., the son of the latter, that he fled to the Moorish court, where, from 1081 to 1085, he gained many brilliant victories over the Christian arms. Again recalled to the Spanish court by Alfonso, who began to feel his value, he was a second time disgraced, and banished about 1090. The Chronicle, which, both from internal and external evidence, appears to be as old as the twelfth century, relates to this second banishment; and though its language is rude, and its rhymes most imperfect, there is a captivating freshness in the scenes which it presents, in its vivacity of movement, and in the occasional traits of poetry which seem to escape almost involuntarily from the writer, that raise it considerably above the ordinary level of such chronicles.

Ballad poetry.

From the date of the poem of the Cid to the reign of John II. (1407–1454), the only monuments of Spanish poetry, at least the only specimens possessing the slightest interest, consist in that vast mass of popular or ballad poetry in which Spain is richer than any other country in Europe. Fortunately the process of collecting and preserving these relics of an adventurous and enthusiastic period, "ere polity, sedate and sage, had quenched the fires of feudal rage," was commenced at a very early period, the first collection having appeared in 1510, under the title of the *Cancionero General*. Not only in numbers, however, but in merit, the Spanish ballad poetry appears superior to that of any other nation of Europe. Everything, in fact, united to give to this species of poetry its freest development. A national character of strong sensibility, excitable yet constant; national pride, in the feeling that they had so long formed the advanced guard of Europe against the Moors, and were daily driving backward the tide of invasion; a life of adventure and gallantry; a strong passion for music and the dance; a delicious climate; a language rich in rhymes, and admitting a species of versification (the assonance), in which "Sponte sua carmen numeros veniebat ad aptos," were here found united. The result has been a collection of ballads of all kinds, warlike, amatory, Moorish (these last chiefly composed after the conquest of Granada by Ferdinand and Isabella in 1492), and satirical, marked by a degree of taste and poetical beauty, of which very few of our English or Scottish ballads have to boast. The Moorish ballads have a peculiar charm, from the richness of the colouring with which they are invested, and their style, which has hit the happy medium between the boldness of some of the old historical ballads, and the over-refinement and affectation of those which were composed after the introduction of the Italian taste into Spanish poetry. The picturesque character of the Moorish life, the natural beauties and artificial magnificence of Granada, the quarrels of the rival families of the Zegris and the Abencerrages, the tournaments, feasts of canes, and other amusements of the luxurious court of Boabdil, afford in these ballads inexhaustible materials for descriptive poetry, a tendency which is hardly to be traced in the earlier ballads. "It is wonderful," says a very eminent Spanish critic, Quintana, "with what vigour and brevity they paint scenes, personages, and feelings. In one it is the Alcayde of Molina, who enters, rousing the Moors against the Christians, who are ravaging their fields; in another, the unfortunate Aliatar, borne back with the gloom of a funeral procession, through the gate from which he had issued with such gaiety the day before; now it is a simple country maiden, who, having lost the ear-rings her lover had given her, weeps at the prospect of the reproaches which await her; and now a shepherd, who, solitary and forsaken, grows indignant at the sight of two turtles cooing in a neighbouring poplar, and drives them away with a stone." Besides the ballads descriptive of incidents, these collections contain many charming little songs and lyrical snatches, vague and undefined, indeed, but often pleasing us even by this very vagueness, which merely suggests a hint to the mind, and leaves the rest to be filled up by the imagination. With few exceptions, the authors of these lyrics are unknown. A few are attributed to the great Don Juan Manuel (who died in 1362), but on doubtful evidence; the writers of the others have died and made no sign.

Though the Spaniards date the rise of their classic poetry from the reign of John II., it is certain this period contains little which has any interest for foreign readers. The pedantic and tedious *labyrinth* of Juan de Mena (1412–1456), a cold and lifeless imitation of Dante's great poem, possesses nothing of a more classical nature than the older poetry, save its form. One poem only of this period, viz. the noble stanzas or coplas written by Don Jorge Manrique on the death of his father, and a few graceful *redondillas* by the accomplished Marquis of Santillana, afford some relief from the pretension and pedantry which generally characterize this period of Spanish poetry.

Introduction of the Italian taste. Boscan.

A great revolution, however, was about to be effected in Spanish taste, by the introduction at once of the measures and of the spirit of the Italian poetry. The close relation into which Spain was brought with Italy during the reign of Charles V. had led to a general knowledge of the treasures of Italian poetry; while many changes in the political constitution and habits of the Spaniards themselves concurred to weaken their attachment to their old and natural romantic poetry, and disposed them to adopt the more regular and polished strains of their Italian neighbours. This change was introduced by Don Juan Boscan (from about 1500 to 1544), who, though he had at first composed and published a volume of poems in the old Spanish manner, had been led, by his acquaintance with the Venetian ambassador Navagero, to the study of the Italian classics, and in consequence formed the design, in conjunction with his friend Garcilaso de la Vega (1500–1536), of introducing to his countrymen the refinements of the Italian versification, and the superior polish of the style of the Petrarchists. But with all Boscan's careful study of the Italian poets, which is evident from the perpetual imitations which his poetry contains, of Petrarch, Bembo, and Sannazzaro, he never could acquire their elegance of taste, nor divest himself of the national tendency to orientalism. Something of the old leaven of impetuosity and hyperbole attaches to his poetry, producing a feeling of incoherence between the matter itself and the medium through which the ideas are conveyed.

Garcilaso.

But what Boscan attempted and imperfectly performed, Garcilaso accomplished with complete success. He was equally distinguished in the field of warfare and of literature. "One hand the sword employed, and one the pen;" and he fell at last, crowned at once with the laurels of poetry and war. In Garcilaso the Italian poets found a rival, if not a superior; for while he adopted their best points, he avoided in a great measure that subtilty of taste which had grown out of the study of the later Platonists, and introduced a metaphysical and reasoning style into those subjects where it was the most out of place. Garcilaso has written little, but that little (at least his Eclogues, for his Sonnets are not of equal merit) is of the highest class; for he has contrived so finely to temper the subtilty of the Italian poets by the more natural warmth of the Spanish, and to clothe his sentiments in words at once so simple and so classically pure, that the result is something superior to any thing that is to be found in his models. In all of them, no doubt, the classic reader will recognize at every turn resemblances to the Latin poets; but these imitations are introduced with so much taste, and fitted with such art into a Spanish framework, that the knowledge that they are imitations rather increases than diminishes our sense of the talent of the poet.

Mendoza.

A third personage was associated with Boscan and Garcilaso in this poetical triumvirate, the famous "tyrant of Sienna," the accomplished warrior, statesman, historian, novelist, and poet, Diego de Mendoza (1500–1575). Mendoza's Epistles, however, betray more rudeness of manner than even the verses of Boscan; and indeed the chief feature of interest which they possess, is the singular spectacle they present of a stern and hardhearted warrior of the school of the Duke of Alva breathing out to his friends Boscan and Zuniga the most fervent aspirations after the domestic happiness of a rural life, or longings for the enjoyment of a philosophical solitude. This feature indeed more or less marks the whole poetry of the period. Whilst the Spanish warriors were distinguished all over Europe for their ferocity, presenting, as Sismondi says, "to the enemy a front of iron, and to the unfortunate an iron heart," we find all their poetry marked with a dreamy, tender, and melancholy spirit. In Mendoza, Garcilaso, and Montemayor, all of whom were soldiers, and conversant with scenes little calculated to soften the affections, we observe this union of practical ferocity with theoretical innocence; nay, even the terrible Duke of Alva appears to have been inspired by the same tastes, and appears in the poetry of the time, not as the ferocious governor of the Low Countries and the organ of the Inquisition, but as the discerning critic, the lover and the patron of literature.

Montemayor.

This tendency to themes of an Arcadian cast gave rise to the Pastorals of Montemayor (1520–1561) and his successors. The Diana of Montemayor, a pastoral romance, interspersed with ballads and canzoni in the style of Sannazzaro's Arcadia, was once amongst the most popular productions of Europe. Its influence may be traced, not only in the host of Spanish pastorals which succeeded it, but in the literature of other countries, in the Astrea of D'Urfé, and in the Arcadia of our own Sir Philip Sydney. Cervantes bestows upon it a sort of qualified praise in his review of Don Quixote's Library, but is disposed to give the preference to the continuation by Gil Polo over the original. Montemayor labours, in fact, under the fault of all his countrymen of the time; he cannot compress; he pours out a stream of musical language, "which runs, and, as it runs, for ever would run on;" but he gives us few ideas that are at once natural and new, and none that stir the heart or strongly awaken the imagination.

The works of Herrera, another poet of this period (1500–1578), on whom the Spaniards have, with questionable propriety, bestowed the title of "the Divine," are in a totally different strain. His themes are religious and warlike, such as the triumph of the Christian arms at Lepanto, or the fatal defeat of Sebastian in his expedition to Africa. Of all the Spanish poets, Herrera, whose mind was deeply imbued with the beauties of the sacred writings, possesses the loftiest style of expression; but the majesty of his diction is often obscured by strange and new creations or combinations of words, while his elevation not unfrequently explodes in palpable bombast. There is a strong resemblance between Herrera and the Italian Chiabrera, both in their beauties and their faults.

The greatest of the Spanish lyrical writers is Luis Ponce de Leon (1527–1591). "More earnest and enthusiastic than Boscan; tender as Garcilaso, but with a soul whose tenderness was engrossed by heavenly, not earthly love; pure and high-hearted, with the nobility of genius stamped upon his brow, but with religious resignation calming his heart, he is different from his predecessors, but more complete; a man Spain only could produce, for in Spain only had religion such sovereign sway as wholly to reduce the rebel inclinations of man, and, by substituting supernal for terrestrial love, not diminish the fulness and tenderness of passion, but only give it another object."[1] The most remarkable feature of Luis de Leon's poetry, is the union of a mystical and religious enthusiasm with the most perfect clearness and transparency of expression. Never was a high and soaring imagination more perfectly under the control of a cool judgment and a critical taste. Whilst a religious Platonism forms the *fond* of his odes, the style exhibits all the terseness, precision, and finish, of that of Horace, of whom, notwithstanding the great differences in their poetical character, he continually reminds us, by the sententious air of his odes, and that serene moral wisdom which drops from him in common with the Epicurean poet, whatever subject he touches on. But the odes of the Spanish poet have a moral grandeur far exceeding those of Horace. The spirit of present enjoyment, or indifference to futurity, which not unnaturally pervades the latter, was revolting to the warm sympathies and devout belief of Luis de Leon. Accordingly, the ideas and images which, to the Epicurean poet, only afford inducements to devote the hours to pleasure, such as the shortness of life, the fading of flowers, or the instability of fortune, the Spanish moralist holds out as inducements to the cultivation of those higher faculties which raise the soul above this world of mutability and misfortune, and prepare it for that purer abode, which he regarded as its appointed home.

The close of the reign of Charles V. is adorned by the great name of Cervantes (1547–1616), more distinguished, however, as a prose writer than as a poet; and by the rise of the dramatic literature of Spain. For a general account of the peculiarly national and remarkable character of the Spanish theatre, which, while it is connected with our own by so many common features, has yet some striking points of distinction, which render its study peculiarly interesting to the admirers of our older British theatre, we refer to the article on the drama. Cervantes, we must admit, appears to mark its *childhood;* for the plots of his dramas are loose, disjointed, and scarcely deserving of the name, though the gloomy grandeur of the Numantia gives it a painful fascination, like the scenes in the town of Hunger in the Inferno. Lope is identified with its boyhood; Calderon, with its maturity and perfection; Moreto, Roxas, De Solis, Mira da Mescua, Da Hoz, and others, who wrote during the reign of Philip IV., with its decline. Invention, high poetry in parts, the power of exciting and maintaining curiosity and suspense, must be accorded to the Spanish theatre. Against these must be set religious bigotry and mysticism, often painfully predominant in the plays of Calderon, particularly in those autos which the German critics have especially selected as the themes of their admiration; the affected and redundant style into which most of their poets were led by the facility of their versification, combined with the habit of working for the stage; and the practice which, upon the Spanish stage, is almost universal, of painting manners and general types of character, rather than discriminating its shades, or giving individuality to the personages represented.

We may here notice, in connection with Spanish literature, the solitary great name of which the kindred literature of Portugal has to boast, Luis de Camoens (1524–1578), who conferred upon his countrymen that which Spain has in vain essayed to produce; for the Araucana of Ercilla certainly does not deserve the title of an epic poem. Viewed in this light, too, it must be admitted that even the Lusiadæ of Camoens is most objectionable; the action flags miserably; the mythology is ludicrous; the morality of some portions of the poem, as, for instance, the scenes on the island which Venus prepares for the refreshment of the returning Portuguese, is more than questionable; but, with all these, the work is inspired and supported by the true spirit of poetry; and its continued popularity and reputation prove how little the real charm or success of an epic depends on the mere plan or machinery of a poem. That which will always render Camoens delightful, is the tenderness of heart which overflows in such episodes as that of Ignez de Castro; and the pride and zealous endeavour with which he labours to embody in immortal verse the spirit of those days in the annals of Portugal, when learning and commerce, warlike enterprise and success, went hand in hand; when De Gama braved the terrors of the Cape, and Alvarez and Albuquerque first launched their gallies into the Atlantic.

Gongora and Quevedo.

From the seventeenth century to the present time, the literature of Spain has been one of decline. Three names only, amongst the many whose works are found quoted in Anthologies and *Parnasos*, deserve notice; those of Gongora (1561–1627), Quevedo (1580–1645), and Villegas (1595–1669). The real talents and rich imagination possessed by Gongora make us lament that, like Marini (from whom indeed he borrowed his manner), he applied them only to corrupt and pervert the public taste. Some of his little Anacreontic verses, songs, and letrillas, written at an earlier period of his life, are models of natural grace and felicity of expression; contrasting most painfully with the ridiculous jargon of language, and *galimatias* of sentiment, which he employed in his later days. The same evil tendency is visible in Quevedo. We have great invention, much acuteness and comic humour, but a lamentable deficiency of feeling and taste. His works have been most justly compared by Bouterwek to a massive ornament of jewellery, in which the setting of some parts is exquisitely skilful, of others extremely rude, and in which the number of false stones and of valuable gems is nearly equal.

---

[1] Literary and Scientific Men of Italy, vol. iii. p. 70.

Villegas A purer taste occasionally appears in Villegas, the Anacreon of Spain, though he, too, seems to labour under the mania of the day, and now and then to run into extravagances worthy of the very wildest of the Cultoristos. After Villegas there appeared no Spanish poet of any originality; for the verses and the pastoral comedy of Melendez Valdez, founded on the episode of the marriage of Camacho in Don Quixote, do not rise above mediocrity; the fables of Yriarte have merely the merit of brevity and neatness of expression; and the comedies of the younger Moratin, the last dramatic works which have attracted any attention, are merely ingenious imitations of Molière. At the present moment Spanish poetry would seem to be absolutely *effete;* nor does there appear much reason to anticipate its speedy revival.

FRENCH POETRY. The present language of France has sprung from that northern dialect which was spoken in Normandy, and known by the name of the Walloon. The earliest compositions in that dialect were romances, founded on some fabulous history, such as Brut of England, which appeared about 1155. **Romances.** To these succeeded the romances of chivalry, from about 1130 to 1190, of which, unless the Portuguese romance of Lobeira, Palmerin of England, be supposed to have appeared before this time, it would seem the Norman-French are fairly entitled to claim the invention. Taking them as a whole, there is no disputing that much fancy and ingenuity are expended upon these now-forgotten performances, though the style is invariably flat and lumbering. They are sustained merely by the high spirit which they breathe, and the happy incidents which the chronicler occasionally introduces.

Allegorical romance. The taste for the allegorical romance was of a date somewhat posterior. Of these singular compositions, the most remarkable is the once celebrated *Roman de la Rose*, begun by William de Lorris, and concluded by Jean de Meun, a poem which was received with boundless admiration, and which continued for a century strongly to influence the literature of Europe. It was at once a romantic and an allegorical poem; a new edition of the art of love, adapted to the moral and metaphysical creed of the middle ages; of dreary length, and yet enlivened here and there by allegorical portraits of imaginary personages, drawn with considerable vivacity and spirit, and by those strokes of satire, or lessons of practical philosophy, which, together with the art of narration, very early began to characterize the literature of France. The conclusion, by Jean de Meun, is inferior to the commencement; it is deformed by a ribaldry and coarseness which justifies the term "niedrige polissonerie," or low blackguardism, applied to it by Bouterwek.

The Fabliaux. But by far the most striking and characteristic part of the early French literature consists in that vast collection of short tales entitled Fabliaux, which were almost exclusively the production of the French provinces lying to the north of the Loire, and which are well deserving of attention, whether their own merits and originality be regarded, or their general influence on fiction. The period of their appearance extends from the last half of the twelfth, through the whole of the thirteenth and part of the fourteenth century, but the greater number are supposed to have been written during the reign of St Louis (1226 to 1270). The compositions of these minstrels differ extremely in character from those of their Provençal brethren of the south of France. The poets of Provence were generally knights and nobles; their themes love or war, or mystical allegoric dreams; and, with much monotony, their poetry certainly presents an elevated and imposing exterior. The Trouvères were generally men of an inferior grade, sprung from the lower ranks of life, in fact literally wandering minstrels. Yet the position they occupied in society was particularly favourable to the promotion of those habits of satirical observation and comic description which constitute the chief attraction of the Fabliaux. Men, in general, of acute and vigorous minds, though destitute of learning and delicacy, and too often of principle; welcome guests in all society from their powers of amusing, yet respected in none, experiencing every extreme of life, and making themselves at home in all; sometimes helping to dispel the ennui of baronial castles, at others courting the society of the humblest vassals, they rambled over the world, harp in hand, as it were, picking up everywhere the materials of their art, and thus painting with a truth and freshness otherwise unattainable, the full-length portrait of French manners during the thirteenth and fourteenth centuries. These light and joyous compositions turn chiefly on subjects of a familiar nature, and consist of stories of knavery and intrigue, and occasionally of those Asiatic legends with which the crusades had by this time rendered Europe familiar. Except, therefore, in invention of ingenious incidents and comic imbroglios, and in a certain tinge of humour and vivacity, which breathes of the sunny skies and vine-covered hills of France, they have little pretensions to poetry. And yet this opinion must be taken with exceptions, for they have occasionally shown that they could excel in themes of a higher kind; and the beautiful and well-known fabliau of Aucassin and Nicollette, by its tender and natural spirit, combined with the deep interest of its situations, throws into the shade the greater part of the more ambitious and elaborate chivalrous romances. We perceive in it all the romantic spirit and deep feeling of the old Spanish ballads, heightened by the graceful naiveté peculiar to the early French poetry.

The period from the commencement of the fifteenth to the sixteenth century is regarded by the French as the transition period of their poetry from infancy to maturity; and the three leading names of the period are Marot, Ronsard, and Malherbe.

Marot. Clement Marot (born 1495, died 1544) is the creator of that school of naive poetry which was afterwards carried to its perfection by La Fontaine and Voltaire. With a playful unambitious grace, he gives a happy turn to every subject, and delights to put the world in good humour with itself. It is justly observed by a French critic, Nisard, that the naiveté of Marot differs from that of any previous poet. In the older strains of the Trouvères and their successors, what we call naiveté often arises merely from the imperfection of the language, and not from any peculiarity in their turn of mind. But Marot wears this air of unconsciousness even in giving expression to ideas the most subtile and recherché; his naiveté seems independent of the language, independent almost of the ideas; it is an emanation of the peculiar genius and idiosyncrasy of the man.

Ronsard It is amusing to contrast the fame of Ronsard during his life (1524–1585) with his reputation at the present moment. His own age elevated him to honours almost divine: in the present how many are acquainted even with a single page of his poems? He was considered the presiding luminary of that constellation of genius which arrogated to itself the title of the French Pleiad; whose great object it was to transplant into French the form and the manner of the lyrics of antiquity; but who succeeded only, as Boileau says, in making a jumble of everything (*brouiller tout*), a patchwork, in short, of Greek and Latin ideas with Italian subtilty of thought and French naiveté of expression.

Malher "Enfin Malherbe vint," says Boileau (1558–1628), like Ronsard a classicist, but endeavouring, and not without success, to seize rather the spirit of the ancients than their forms. Of the higher inspiration of the ode he had little; his march is stately enough, but it is measured and slow; he has little or no enthusiasm, but, in all that regarded the judicious treatment of a subject, or the minutiæ of language or versification, he was well fitted to be the legislator of that new and more sober school of composition which superseded in France the extravagances of Ronsard and his satellites. The three pieces of Malherbe which appear to indicate the highest talent, approaching indeed to genius, are the Ode to Henry IV. on the taking of Sedan, the Ode to the Queen-Mother, and the beautiful verses addressed to the Councillor Duperier on the sudden death of his daughter. Few lines could be selected more beautiful than the following stanza from the latter:

Mais elle estoit du monde où les plus belles choses
  Ont le pire destin;
Et Rose, elle a vecu ce que vivent les roses,
  L'espace d'un matin.

But she was of a world where fairest things
  Have foulest doom:
Rose as she was, she had a rose's life,
  A morning's bloom.

e of
uisXIV.

We now arrive at the period which is, or rather was, considered by the French as the golden age of their poetical literature, the long reign of Louis XIV. Everything at this time concurred to impress on poetry that stamp of stateliness, polish, and courtier-like adoration of monarchy, which at that time pervaded French society, and which exerted so powerful an influence on the general tastes of Europe. The French monarchy had now been consolidated by the firm hand of Richelieu, who, whilst he unrelentingly pursued his design of lowering the aristocracy and exalting the throne, was not insensible to the claims or the importance of literature, and had been the first to give it the support which a corporate character appeared likely to afford, by the formation of the celebrated academy. The troubles of the Fronde were over. The heats and animosities of rival religions had been appeased by the edict of Nantes. The personal character of Louis was well suited to effect his main object, which was to render his court a model for the imitation of the world. Of limited abilities, without talent either for warfare or diplomacy, he possessed tact enough to perceive at once his deficiencies and his advantages; and, endowed with many of the most attractive outward graces and accomplishments of a king, he played the part of a dignified monarch with much discretion and ability. Thus wielding, without opposition, the energies of a powerful kingdom, and collecting around him at his court all that France contained of intellectual ability, a tone of courtly polish and extreme refinement was imparted to society, which soon impressed its traces upon literature, 'partly for good, and partly for evil. The influence exercised by French manners and French literature upon other countries became paramount and unprecedented, superseding the most inveterate usages, overturning the strongest national prejudices, and establishing a despotism more universal than had been known in literature since the downfall of Greece and Rome.

The most imposing shape in which poetry appears during this supposed Augustan period of French literature, is in that of the drama; which, commencing with the rude plays of Jodelle (who died in 1560), reached its perfection during the close of the reign of Louis XIII. and the reign of Louis XIV., in the tragedies of Corneille and Racine, and the exquisite comedies of Molière. For a full account of the French stage we refer to the article Drama.

It cannot be said that, in any other department of poetry except that of the drama, the age of Louis XIV. was pre-eminently distinguished; for the artificial and hollow refinement of the time seemed unfavourable to that vigorous and natural feeling which should speak in poetry, with a corresponding strength and originality of expression. Yet two names impress themselves, by their strongly discriminated traits, upon the memory,—La Fontaine (1621–1695) as the reviver of the old naive style of Marot, though with a degree of polish and grace of which Marot had no conception; and Boileau, as the representative of that school of terse morality, sound sense, and wit, mingled with and heightened by fancy, of which Pope is the best example in English poetry.

La Fontaine.

With all the levity and licentiousness which deform the Contes, there is no denying to La Fontaine many of the best qualities of the poet; knowledge of the world, which yet does not impair his bonhommie and kindness of heart; a humour playful, gentle, continuous, never pushed to excess, combined with tenderness, with a disposition to reverie and pensiveness; a strong sensibility to the beauties of the country, of which his descriptions, though short, are always striking, and marked by that just selection of points and clear local portraiture which we find in Crabbe, and which show that he made his studies for them on the spot; the whole heightened and set off by a style apparently simplicity itself, but which must have been, as we know it was, the result of the most laborious polishing and elimination: all these give an extreme charm to the Contes, and perhaps still more to the Fables, of La Fontaine; for the Contes, though their licentious gaiety has made them more generally known, display to less advantage the peculiar qualities of La Fontaine's genius.

Boileau.

Boileau, again (1636–1711), pleases and must always please, although by qualities the most opposite to those of La Fontaine; namely, by awakening a calm emotion of intellectual satisfaction, rather than by any excitement of the imagination or the feelings. As Racine represents the tender and voluptuous side of French manners and character during the age of Louis XIV.; as La Fontaine embodies in his tales and fables its easy tone of moral indifference and *malice*, masking itself under the disguise of simplicity; so in Boileau we find, arrayed in a dignified and philosophical dress, its better points, its good sense and sagacity, its lively perception of the eccentric and ridiculous, its love of external decency, order, and propriety, both in morality and in literature.

In his Lutrin he even displays a considerable degree of invention, though chiefly of a comic kind; for, though not destitute of a sense and feeling of high poetry, he was essentially deficient in any actual power of dealing with such themes; and, with that tact and judgment which distinguished him, he has rarely, save in his most unfortunate Ode on the taking of Namur, which has been so justly but so unmercifully parodied by Prior, ventured within this province of poetry. Within his proper field of moral censorship, or of the mock heroic, arrayed in all the graces of elegant diction and classic allusion,—or the poetical abridgment, in the most condensed and pointed form of the approved critical canons of the time,—he is assuredly without a rival in French poetry, and, with the exception of Pope, in European literature.

Eighteenth century.
Rousseau.

The literature of the eighteenth century in France is more distinguished by its prose than its poetry. Prior to Voltaire, at least, in whom great and versatile powers of mind, approaching if not attaining to high genius, must be admitted, it added nothing of substantial value to the contributions of the age of Louis XIV. At one time indeed the odes of J. B. Rousseau (1669–1741) were extolled to the skies, as models of lyric poetry; and Voltaire certainly speaks of them in terms of extravagant praise. To any one now perusing them, with the recollection of the great models of antiquity before him, or even testing them by the simpler process of his own feelings, they will assuredly appear totally deficient in genuine inspiration. The enthusiasm is imitative and factitious; the imitation dexterous, no doubt, but yet palpable to every one who possesses any real poetical sensibility; the thought is often propped up by the words, not the words elevated and quickened unconsciously by the vital grandeur of the thought. What true lyric enthusiasm, indeed, could reside in a mind which busied itself alternately in the composition of rapturous religious odes, and epigrams of disgusting obscenity?

Chaulieu and Gresset.

Much more of real poetry, because accompanied by nature and simplicity, is to be found in Chaulieu's pastoral lyrics; in some of the little romances of Moncrif, such as Alexis and Alix, which abounds with lines that by their truth and simplicity of expression have become proverbial; or in Gresset's pleasing stanzas on the golden age, or even in his lively tale of Vert-Vert.

Voltaire.

The reputation of Voltaire (1694–1778) at the present day rests more upon his witty and amusing prose than upon his poetry. That didactic tendency which was the spirit of the age, that attempt to make all the creations of poetry subservient to inculcating certain philosophical opinions, appears in all the poetry of Voltaire; it speaks even in Mahomet and in Zane, as much as in his graceful occasional verses, his Tales in the manner of La Fontaine, or his epistles. "Les François n ont pas la tête Epique," was his own expression; and the Henriade certainly went far to prove the fact. It is the mere *simulacrum* of an epic; hard, laboured, soulless. It is most unfortunate for Voltaire, that the poem in which his versatile abilities have been displayed to the greatest advantage, is one which its indecencies and impieties have in a great measure banished beyond the pale of literature.

About 1770 may be noticed the rise of the descriptive school of poetry, in the poems of St Lambert and Delille; an importation in all probability from England, where a similar taste had been introduced by the success of the Seasons of Thomson. From 1730 to the commencement of the present century, numerous attempts were also made to confer on France something that should merit the title of an epic poem; but without the slightest success.

During the despotism of Napoleon, poetry appeared to be almost silent. With the restoration of the Bourbons appears the rise of that romantic school, the growth of the fermentation of the revolution, and of that removal of the old landmarks both in polity and opinions which it caused; a school which, both in theory and practice, repudiates the principles of the old French classicists, and has certainly effected a complete revolution in the literary tastes of the time. Whether much or anything has been gained by the change, is in the highest degree questionable. Calm observers think the French have injudiciously sacrificed their reputation for correct and classic execution, for wit and good sense, in the search after those higher qualities of lyrical inspiration or epic grandeur which nature appears to have denied to them. We do not speak of the revolting extravagances in which the leaders of the romantic school, at the head of whom stands Victor Hugo, have indulged. The public taste of Europe, and latterly of France, has so strongly revolted against this convulsionary school, that it cannot long maintain any hold over the national mind; but we fear that, even when the worst extravagances of the new school are retrenched, there will remain a permanent injury to the national taste, in the loose, disjointed, and barbarous style, with the total want of all logical plan in composition, which these innovators have introduced.

Beranger.

Yet it is pleasing to close this short notice of French poetry with the name of one who, though partaking of all the modern influences of his time, is yet within his own department, that of song, a genuine classic. In this department of the lyric, France has always been distinguished. In that country not only has it constituted, as elsewhere, the amusement of the lower classes, but it has long attained the dignity of a powerful political agent; its monarchy was justly described by Champfort as a despotism tempered by songs. Of all the modes in which poetry can be made subservient to purposes like these, song is the most effective, universal, and immediate in its operation. It speaks not to a particular class, but to all; its brevity fixes it in the memory; the creature of the moment, it avails itself of every allusion, every passion, every prejudice of the day; while its outward form appears so trivial and harmless, that even despotic governments are deterred, by the fear of ridicule, from attempting to interfere with it. Beranger, whilst he selects the simplest, the most universal feelings, the most familiar sentiments and images, provided they are true, unforced, and natural, yet, by the tact and skill which he employs in their treatment, and the felicity of their expression, invests them with quite an original character. The oftener a thought has occurred to others, so much the better with him; for it is an evidence of its truth, and of its power of affecting the heart. What remains for him, and what he performs, is to impart to this thought, so familiar to all, though perhaps vaguely and indefinitely, form, colour, expression, so that when presented by him to our notice, it is felt at once to be an old acquaintance, and yet awakens all the curiosity and interest with which we regard a new one. His originality, in short, lies entirely in his application of the idea, and the point and compactness with which the image is brought out by his hands. His success in these respects is great; but it is a success attained, as may be imagined, by the most patient revision. He is said to be an extremely slow composer, frequently laying aside the subject on which he is employed for weeks, and patiently waiting, till, by dint of long reflection on the subject, and careful polishing, by the selection of the happiest allusions, by the studious elimination of every phrase or illustration that appears recherché or ornate, he has given to the whole that unity and appearance of ease and simplicity at which he constantly aims.

GERMAN POETRY.

We have noticed the early development of German heroic song in the Nebelungen and the Heldenbuch; and the introduction of the Provençal taste under the Suabian emperors in the poetry of the Minnesingers. In all its leading features the poetry of this period (1138 to 1346) corresponds with that of the French Troubadours, with this unfavourable distinction, that the poetry of the Minnesingers (love-singers) is much more exclusively devoted to amatory themes than that of the Provençals, which blended with these, warlike and patriotic or satirical effusions. Hence their monotony of effect, when we peruse any of these collections at once, is undeniable. Schiller has, accordingly, in a passage of unusual severity, denounced their poverty of ideas, and says, that if the sparrows were to compose an "almanack of love and friendship," it would probably bear a close resemblance to these cloying strains of the Minnesingers. But against this sarcastic remark must be placed the observations of Frederick Schlegel. "The impression of uniformity arises from our seeing these poems bound together into large collections, a fate which was probably neither the design nor the hope of those who composed them. But, in truth, not only love-songs, but all lyrical poems, if they are really true to nature, and aim at nothing more than the expression of individual feelings, must necessarily be confined within a very narrow range both of thought and sentiment. The truth is, that great variety in lyrical poetry is never to be found, except in those ages of imitation when men are fond of treating of all manner of subjects in all manner of forms. Then, indeed, we often find the tone and taste of twenty different ages and nations brought together within the same collection, and observe that the popularity of the poet is increased exactly in proportion as he descends from his proper dignity, when simplicity is sacrificed to conceits and epigrams, and the ode sinks into an occasional copy of verses."

The opening of German poetry, then, had been, on the whole, brilliant and promising; but the confusion, insecurity, and violence, which followed the death of Frederick II. in 1250, seemed fatal to the progress of improvement. After Rudolph of Hapsburg, we perceive in its poetry a visible decline. The Minnesingers were succeeded by the Mastersingers, personages who seemed to think poetry was to be acquired like any other trade, and to be supported and kept alive by guilds and corporations. It is difficult, perhaps, to point out at what precise period the former school of poetry ends, and the latter begins; they melt into each other like the colours of the rainbow. But the character of the two schools, taken in the mass, is very different: for, in place of the tender, thrilling, amatory spirit of the Minnesingers, the great object of the poetical craftsmen who succeeded them was to give a didactic and philosophical air to their compositions, and to substitute for fancy and feeling, common-place truisms and moral aphorisms. One work only of this period deserves notice, not indeed on account of its high poetry, but of its shrewdness, its effective satire, and its invention, the comic epic, as it may be called, of Reynard the Fox, the groundwork of which, no doubt, existed before in other countries; but the novelty of the treatment of the subject by the German or Frisiac writer, and the great superiority of its execution, entitle it to the character of an original work.

From the close of the fifteenth to the middle of the eighteenth century, a dreary blank intervenes in the poetical annals of Germany. Bouterwek has, indeed, devoted more than a volume of his valuable work to this period; but, whatever interest the minute detail of second-rate names may have for Germans, there is certainly little or nothing calculated to awaken the least interest in the foreign reader. The effects of the thirty years' war were felt in Germany, paralyzing science, general culture, and the spirit of poetry, up to the time of the peace of Westphalia. Opitz and Flemming are the only poets who rise above the dead-level of the mediocrity of the time. Opitz was a great importer from other countries, many of his poetical consignments being derived from Holland. Yet, though not a man of original mind, his strong good sense, a sincere honesty of mind, and a patriotic inspiration, render his poetry even now readable; though probably few are disposed to concur with F. Schlegel in preferring his style to that of Klopstock. Flemming is an inferior poet to Opitz, and yet perhaps his poetry is more interesting, precisely because it is more personal; because it lets us into the secret of his feelings, his friendships, and attachments. Hoffmanswaldau and Lohenstein enjoy the evil distinction of having corrupted, by the most false and fantastic taste, that poetry which was already but too destitute of any great pretensions. The period from 1648 to nearly 1750 is characterized by Schlegel as the age of barbarism, a chaotic interregnum in the history of German literature. Poetry existed in no other shape than that of feeble imitations of the French, profuse of mythology, penurious of feeling, destitute of nationality. "Apollo," says Menzel, "sat on the German Parnassus in a full-bottomed peruke, and, with fiddle in hand, led the concert of the well-powdered muses."

K stock.

When at last the German muse began to arouse herself from her torpor, and to "awake a louder and a loftier strain," she received no countenance from royal patronage. The great Frederick despised and disliked the literature of his countrymen, and seemed to think there was no hope for poetry, save in a slavish adherence to the spirit and the rules of the French. If Klopstock (1708–1803) had done nothing more than awaken the feeling of nationality by his poetry, and teach his countrymen that, in the free and independent cultivation of their own genius, and the selection of their own themes, lay their only chance of redeeming Germany from the state of torpor into which its poetry had fallen, he would have conferred an inestimable service on its literature. With the Messiah, Schlegel thinks the modern poetry of Germany may be said to have begun, so great have been the benefits which it has conferred in regard to style and expression, as well as in the spirit of nationality and religious feeling which it imparted to the poetry by which it was succeeded. The plan, indeed, labours under great and insuperable defects. The mind of Klopstock was but ill suited to the epic; it was eminently lyrical and elegiac. Nor can it be denied that there is a degree of rhetorical pomp and long-windedness about his style, which becomes frequently oppressive, and communicates an air of pedantry to his poem. Still Klopstock has exercised an important and beneficent influence upon German literature; he taught his country its own strength, and freed it at once and for ever from the leading-strings of foreign authority.

Wieland.

Wieland (1733–1813) is more French in character than Klopstock, or rather he blends the luxurious and somewhat licentious spirit of the Italian romantic poets, with that tone of gay and heartless philosophy which the example of Voltaire had introduced into French literature; and yet, withal, he is no mere imitator, but possesses a decided individuality in his later and better works, and even a truly German spirit. The tendency towards the imitation of the French appears, however, chiefly in the earlier productions of his romantic muse, such as the Idris and Zenide, the New Amadis, and others, in which he has assailed with such persevering satire the Platonism of love. As he advanced in life, he began to entertain better views: he grew dissatisfied with that epicurism which he had inculcated as the basis of conduct, and that licentious gaiety which he had made the mainspring of his poetry; and in his Oberon he endeavoured to make amends for the levity with which he had treated the better feelings of the heart, by those charming pictures of conjugal love, true constancy, and chivalrous heroism, which, combined with the beauty of the descriptions, and the pure and simple flow of the style, have rendered the Oberon the only successful effort in later times to revive the tones of that Italian harp which has slumbered since the days of Ariosto.

Gessner.

Gessner (1738–1788) belongs to this period. His Eclogues at one time enjoyed great popularity; and he has certainly in some of them, such as the First Navigation, displayed fancy and invention. But he deals in a species of poetry too remote from actual life; and there is a sort of sheepish modesty about his shepherds, and French coquetry about his nymphs and shepherdesses, which communicate something of a ludicrous character to his Arcadia.

Lessing.

The fame of Lessing (1721–1781) must rest more upon his vigorous, transparent, logical, and delightful prose style, than upon his poetry. His dramas, with the exception of Nathan the Wise, are written in prose; and the style of Nathan scarcely rises above the conversational pitch, though its Brahmin-like simplicity of tone, and the air of mild and tolerant wisdom which pervades it, leave a pleasing impression on the memory.

Schiller, Goethe.

The two greatest names in German literature succeed, namely, Schiller (1759–1805) and Goethe (1749–1832). Of their dramas we have spoken elsewhere. Schiller, however, though greatest as a dramatist, is entitled to nearly equal eminence as a lyric poet. His odes, his short poems, mingling so much philosophy with so much feeling; his charming ballads, pitched on every key, from the simplicity of the Toggenburg and the Fridolin, to the rude force of the Diver, the fine chivalrous and devotional tone of the fight with the dragon, and the classic finish of the complaint of Ceres, or the cranes of Ibycus; would alone have been sufficient to place him second only to Goethe, had he never written William Tell, or the Maid of Orleans, or

Wallenstein. In one particular he must rank far higher than Goethe; in the elevated aim which he always had in view; the attainment of noble ends by noble means; the rendering poetry what it always ought to be, not a mere specimen of plastic ingenuity, but something by which the soul feels itself refined and the heart made better. His enthusiasm, impetuous, and yet tender and affectionate, clothed all the universe, moral and material, with forms of grandeur, and gave to all he uttered the stamp of purity and truth. "His greatest faculty," says the most eloquent of his biographers, "was a half poetical, half philosophical imagination, a faculty teeming with magnificence and brilliancy; now adorning or aiding to erect a stately pyramid of scientific speculation, now brooding over the abysses of thought and feeling, till thoughts and feelings else unutterable were embodied in expressive forms, and palaces and landscapes, glowing in ethereal beauty, rose like exhalations from the bosom of the deep."

Of Goethe we have already so very fully expressed our opinion (see the article GOETHE), that we shall not again enter upon the subject.

At the present day the aspect of German poetry is not the most imposing. Tiek, who had evinced high talent for the Mährchen, or Legendary Tale, to which he communicated all the charm of earnest belief, and the most musical versification, has for some time past exchanged poetry for prose and polemical discussion. Uhland and Ruckert are at this moment the most eminent among the German lyric poets; for the effusions of Heine, wretched attempts to infuse a sneering imitation of Byronism into lyric poetry, have already, we believe, survived their popularity. The host of poets, besides these, is numerous, but not of any marked excellence or originality. Judging from a few of his compositions, we should be disposed to say there was more of poetical genius in Leopold Schefer, than in almost any of his contemporaries.

ENGLISH POETRY.

It is not our intention to enter into any minute details as to English poetry, with which we shall conclude the present sketch. Since we have already noticed, under separate heads, most of the individuals by whom it was adorned, we shall merely attempt to indicate generally the directions taken by poetical taste at different periods of our annals.

Even prior to the Norman conquest, we know from William of Malmesbury, that England, like all the Gothic nations, had been possessed by a large mass of ballads, written in Anglo-Saxon, though, as no fragments of these remain, we know nothing of their poetical merit. This earlier minstrelsy must soon have sunk into discredit, or been entirely suppressed, by the Norman conquest.

The English language, as it now exists, grew out of the mixture of the Anglo-Saxon with the Norman, and seems to have acquired a complete form by the middle of the thirteenth century. In 1297, we have the Rhyming Chronicle of Robert of Gloucester, the first undoubted composition in the English tongue.

From the Norman conquest to the time of Edward III., the literature and poetry of England consists of little else than translations from, or imitations of, the Norman romances and chronicles; and, judging from the ridicule with which they have been assailed by Chaucer in his Rhyme of Sir Thopas, they must have been of slender merit, since they are represented as shocking the taste, of course not particularly refined, of the host of the Tabard. The distance, at all events, which separates all our English versifiers of this period from Chaucer (born 1328, died 1406), is such as justly to entitle him to the honour of being the first of English poets, the sun that "flames in the forehead of the modern sky;" throwing out a splendour that showed at once his own lustre, and the dreary wastes that spread far and wide towards the literary horizon.

Chaucer.

Much of Chaucer's time, however, was wasted in the school of those French allegorical poets, whose romances were at one time so influential in Europe. In fact, nearly half his life, as Mr Campbell remarks, was passed amongst the dreams, emblems, flower-worshippings, and courts and parliaments of love, of that visionary and tiresome school. He was fifty-four years of age before he commenced the Canterbury Tales, in which alone the peculiarities of his genius, its originality, and its extent, can be said to be completely manifested. This late discovery of the true bent of his powers is singular; for Chaucer appears peculiarly marked out as the poet, not of mysticism and allegory, but of clear observation of life, and of practical aims. In the Canterbury Tales, which were obviously suggested by the influence of Boccacio's Decameron, he first found full scope for the display of the various qualities of his mind, and of that mass of real knowledge of life with which his experience of society, in all its aspects, high and low, from the palace to the cottage, at home and abroad, had supplied his mind. His clear observation, and corresponding power of clear painting, giving the most vivid picturesqueness to all his delineations; his quiet and unobtrusive humour; his satirical power, at once forcible and delicate (a combination peculiarly rare in that stage of struggling and imperfect civilization); his imagination sufficiently elevated, yet always regulated by good sense; a cheerful contented tone of feeling, which makes him impartial towards all the world; a power either of creating character, or of so artfully and harmoniously putting together the result of his actual studies of men, as to give to these all the free and natural effect of a creation; all these qualities found fit scope for their exercise in the broad, varied canvass he selected, which, by means of its ingenious framework, of a pilgrimage embracing persons of both sexes and of all ranks, and enlivened by tales told to relieve the tedium of the way, admitted equally of the comic and the tragic, the high and low; themes of chivalry and mythology, like the Knight's Tale; tales of wonder, blending oriental marvels with the romance of the West, like the Squire's; or stories of English low life, like the Miller's or the Reve's. The versatility of talent, indeed, displayed in the Canterbury Tales is astonishing; and, as in the case of his Italian rival, Boccacio, it is difficult to say whether it is in the comic or the tragic that Chaucer most excels.

In invention, so far as regards incident, the English poet and the Italian novelist may be placed nearly on a par; the woodland freshness and beauty of Chaucer's forest scenes, may be equalled by the charming country landscapes in which Boccacio places his interlocutors; but in power of characteristic delineation, particularly by those minute strokes of Dutch painting which present the exterior of objects, or those happily selected traits which at once mark the individual, Boccacio cannot sustain the least comparison with the father of English poetry. He has many faults, but they are the faults of his age; the faults of coarseness of taste and manners, of inartificial plans, of prolixity of style; the natural errors to which the infancy of poetry, destitute of models, and struggling with an unformed language, was exposed. Against these must be placed the advantages of a vocabulary in which words are pictures, of subjects of description, unhackneyed, and bright with all their primitive freshness; the wisdom or grave humour of the philosophic observer blending most cunningly with the *bonhommie* and the garrulous graces of the narrator; an easy *abandon*, both as to matter and manner, which has its charm, however little reconcileable with the more artificial treatment which criticism would suggest; nature painted without exaggeration, as without disguise; and withal that feeling of unity imparted to the whole, which makes the most discordant elements unite in kindly harmony, and which is never found except in the productions of the highest minds.

The appearance of Chaucer in English poetry has been well compared by Warton to the early appearance of a bright and genial day in an English spring; exciting the brighter hopes of a speedy and balmy summer,—hopes which are almost immediately blasted by the return of frost and tempest, and the settling down of winter, as bleak and blighting as before. In English poetry that effect was produced by the disastrous period of the wars of the Roses.

From the time of Chaucer almost to that of Spenser, certainly no progress is made; or rather, if the language in some degree advances, the spirit of poetry retrogrades. Gower was his contemporary, Lydgate followed immediately after him; but they belong, so far as regards poetical genius, nay even poetical dexterity, to a previous century. In truth, the first introduction of learning into England appears to have been unfavourable to poetry, giving rise to pedantic imitation in place of independent efforts of genius; a tendency which, indeed, to some extent, is visible even in the finest poetry of the Elizabethan period. By far the most distinguished name, indeed, between Chaucer and Spenser, is that of the Scottish poet Dunbar, who, in humour and power of character-painting, greatly surpasses Gower, and approaches to Chaucer. The poems of Surrey, and Wyatt, and Sackville, who followed during the reign of Henry VIII., can be regarded only as proofs that the love of poetry had not ceased to exist, and that in some shape, however rude, its voice was struggling to make itself heard in that calmer and more settled state of the political atmosphere which had followed the union of the rival houses in the persons of Henry VII. and Elizabeth of York.

Age Elizabe

But when Spenser arose to enrich English literature with another great work of original genius, many causes, which had probably at first acted unfavourably for the progress of poetry, were beginning to exercise a more salutary operation. The Reformation, which had at first produced tumult, bloodshed, and wide-extended distress, by the suppression of those great hospitals, the monasteries, was now beginning to bring forth its better fruits, in the shape of a free and inquiring spirit, carried into all departments of thought and imagination. That acquaintance with the treasures of ancient learning, or the classic poetry of modern Italy, which had at first tended to overpower and confuse the national mind, was now turned to better account; it had insensibly refined the taste, and made the purest models of preceding times familiar to the poet and the scholar. The spirit of chivalry, still lingering in the English character, had been aroused into new and active existence by the triumphs which had attended the national arms during the reign of Elizabeth. A love of adventure had been generated by the frequent expeditions into remote countries and climes, as to which, in that imperfect state of geographical and physical knowledge, marvels were believed, as incredible as any that figure in the pages of Sir John Mandeville. There was, in short, at this period, a remarkable union, in the English character, of the sober qualities of strong intellect with deep convictions and high imagination; a character which manifests itself in every department both of poetry and literature.

Spen

Born in this happy period, and educated under such influences, Spenser (1510–1598) produced his great poem of the Fairy Queen. Familiar with Italian literature, as well as with the best learning of antiquity, it was from the works of Ariosto and Tasso that he had derived his bent towards chivalrous poetry. But the deeper earnestness of his character prevented him from treating his subject with the levity of Ariosto. Chivalry was to him a principle of faith, a part of religion, not the mere fantastic framework in which successive pageants of love and war, or luxurious description, were to be enclosed. In England it had not assumed that outworn and almost comic air which it wore when Ariosto first took up the entangled threads of Boiardo. It had still a vital influence on society, and ran like a thread of silver tissue through the coarser web of life. Nay, even the religious spirit in which Tasso had conceived the Jerusalem, scarcely satisfied the mind of Spenser. He would render every incident which he described a step in some high argument or moral demonstration; every character the embodied representation of some virtue and vice; all the visions of imagination subservient to the cause of religion. He would enlist all the restless and excursive intellect, and adventurous feelings of an ardent and romantic age, under the banner of purity and goodness.

> That with the glory of so goodly sight,
> The hearts of men that fondly here desire
> Faire seeming shews, and feed on vain delight,
> Transported with celestial desire
> Of those fair forms, may lift themselves up higher,
> And learn to love, with zealous humble duty,
> Th' eternal fountain of that heavenly beauty.

And so deeply does this principle pervade his poems, that, whilst wandering among the scenes of enchantment with which he surrounds us in that spiritual region to which he gives the name of Fairy Land, we can never forget that they have a spell beyond their first outward significance, nor be insensible to that still small voice of piety and wisdom, which speaks through all those creations of his genius, and whispers that the place whereon we are standing is holy ground.

It must be admitted, however, that if this under-current of allegory gives a degree of solemnity and moral grandeur to Spenser's poem, its effects in other respects are unfavourable. It does occasionally interfere with the natural movements of the imagination, gives a formal and metaphysical air to the conceptions of the poet, and, by rendering the characters abstractions of moral qualities, impairs their individuality as human beings. So far the injurious effect of Spenser's allegorical plan can hardly be denied; but it is absurd to speak of the allegory in Spenser being so obtrusive and continuous as altogether to destroy the interest of the poem as a representation of romantic life. The fact is quite different. Occasionally, no doubt, in the personifications of Envy or Pride, or the siege of the Castle of Temperance, in which the barriers of hearing, sense, smell, taste, and touch are represented as successively assailed by troops of monsters from without, the allegory is too prominent; but assuredly it sinks entirely out of view, and is perceived only on subsequent reflection, in the deep human interest of all the finer passages of the poem, such as the remorse of the Red Cross Knight, his temptation by Despair; the wanderings of Una, with her angel face "making a sunshine in the shady place;" Guyon's visit to the cave of Mammon, and his trial in the gardens of Acrasia; the combat of Campbel with the three brothers; or the many other passages, which must be impressed upon the memory of every reader.

An extreme sensibility, almost amounting to a luxurious love of beauty, a flush of colour in his descriptions, which has led Mr Campbell to compare him to Rubens, and a fancy of the most remarkable exuberance, are the leading qualities of Spenser's mind. In this prodigality of fancy, indeed, lies at once the strength and the weakness of Spenser: for while it infuses life into all his pictures, making the plumes of Prince Arthur wave like the almond-tree on the top of Selinis; or the face of Britomart, when she raises her vizor, like the moon breaking forth in darksome night from behind the noisome cloud in which she was enveloped; so, on the other hand, it leads him occasionally to revel in images and traits which are painful, or even physically revolting, such as the portrait of Gluttony, the loathsome vomit of Envy, or the minute description of the operation of Diet and Appetite, Concoction and Digestion, with some other inmates of Castle Temperance. His fancy may indeed be compared to the Nile in its overflow, disdaining the confinement of banks, and spreading around a luxuriance of soil, alike productive of the flower and the weed.

In the portraiture of the allegorical beings introduced, Spenser is admitted to be without a rival. In his hand they almost cease to be mere abstractions of good and evil qualities, so life-like is the form in which they are presented, so picturesque the garb and accompaniments with which they are invested, so natural the gestures, actions, and occupations, attributed to them. They appear the natural inhabitants of this realm of enchantment, raised as it is many degrees above the level of reality, bright in the near ground, with the sunniest tints of fancy, and fading away in the distance into the most aerial and heavenly hues.

The language of Spenser seems to be steeped in music; he is the greatest master of the difficult art of employing alliteration with success; his versification unites in the highest degree melody with majesty. It is formed on the principle of the Italian *ottava rima;* but, by the addition of the Alexandrine, it possesses a sonorous grandeur in the close which the Italian stanza wants. "It has not," says Mr Hazlitt, "the bold dramatic transitions of Shakspeare's blank verse, nor the high varied tone of Milton's; but it is the perfection of harmony, dissolving the soul in pleasure, or holding it captive in the chains of suspense. Spenser is the poet of our waking dreams; and he invented not only a language, but a music of his own for them. The modulations are infinite, like those of the waves of the sea; but the effect is still the same, lulling the senses into a deep oblivion of all the jarring noises of the world."

In the hands of Spenser, the allegorical form appears invested with all the brightest colours of the fancy. In the works of most of his contemporaries it appears lifeless and pedantic. A disagreeable mixture of stilted expression and false learning blends with and alloys most of the poetry of the time. It deforms the otherwise noble lines of Sir John Davies, and renders Silvester unreadable. Shakspeare is not free from it; for it was deeply inwoven with the national taste of the time, and showed itself in the language of ordinary conversation no less than in poetry. Yet it is delightful to find the greatest dramatist also the greatest lyrical poet of his age; for, after Spenser, what work of that time will bear the least comparison with Shakspeare's sonnets? Sonnets they are not, in the strict Italian sense; but for condensation of imagery, for natural thoughts, clothing themselves in the aptest expressions either of majesty or melody, without any redundance of expletives, or rank luxuriance of epithets, they leave Petrarch and his imitators at a distance. A singular grace, and even dreamy beauty, surprises us in the masques of Ben Jonson; because it contrasts so strangely with the otherwise hard and saturnine turn of his mind. A few gems, amidst much that is coarse or quaint or indifferent, may be gleaned from the pages of Herrick; power and vigour, mixed with sectarian gloom, and deformed by extreme ruggedness of versification, are visible in Quarles. The rise of satire appears in the works of Hall and Donne, of pastoral in Browne; while sacred poetry finds no unworthy representatives in Giles Fletcher and Crashaw. A lighter and gayer taste, a more level, but natural expression, shows itself in the compositions of the cavalier poets of the court of Charles I., in the graceful little airs and verses of Carew, Lovelace, Davenant, and Suckling. In particular, to them we are indebted for some of the best of the few good songs we possess in English; witness the "He that loves a rosy cheek" of Carew, and the song written by Lovelace during his confinement in Westminster, "When love with unconfined wings hovers within my gates." To Denham and Waller, particularly the latter, have been ascribed by Johnson the glory of improving our English numbers. It would be more just to say, that they had the good sense to perceive the importance of this element of poetry, as Spenser had done, while their contemporaries too much neglected it. Almost all the poets above mentioned have been classed by Johnson under the title of the metaphysical poets; a title of doubtful application as to any of them, but which, if it be applicable to Cowley, whom he considers their chief, can scarcely be very accurate when applied to Suckling and Waller. Cowley is simply a poet in whom the fancy, while it is teeming and fertile, is seldom warmed by passion or directed by judgment; whose miscellaneous learning oppresses and buries his taste; and who therefore wearies us even at the moment he impresses us with the consciousness of his great resources and his mental powers.

Change produced by the civil war.

A great change in the character and spirit of poetry followed the convulsions which closed abruptly the reign of the first Charles. The poetry of that court leant towards the elegant, the romantic, the fanciful, the brilliant, and witty; but the stronger passions which had been awakened, the deeper interests which had been put in hazard, by the civil war, had soon impressed a character of solemnity on all literature, and made poetry itself, following the fashion of the time, assume a polemical, ascetic, sometimes mystical, yet grand and enthusiastic character. In those whose tastes were formed only after the change, this polemical character, and this proscription of certain subjects or associations, to which puritanism led, would probably have damped the wing and narrowed the flight of imagination; and accordingly no great poet appears to have been reared in that rigid and prosaic school. But the tastes of Milton, the great poet of this period, had all been formed in an age and a school more favourable to the exercise of the imaginative powers; his exquisite lyrics, and his Comus, had already been written before he visited Italy in 1638, at the very time when Carew, and Suckling, and Davenant were in the height of their popularity and reputation. Ere his great epic poem appeared, he had witnessed and deeply shared in the agitating struggle which had ended in the temporary subversion of the monarchy, and the stern but imposing despotism of Cromwell; and thus educated in the former period, and as yet witnessing the best bloom and flush of the latter, he united the chivalrous recollections of the Elizabethan age, and the classic associations with which his early education had filled his mind, with the enthusiasm of principle and intensity of will which characterised the men of the Parliament. Milton represents more vividly than any other the wide sweep and overpowering force of those political and religious sentiments which agitated the age; for all his earlier leanings were visibly directed towards the romantic and gorgeous associations of the past, towards the pride and pomp of chivalry, the well-trod stage, the throngs of knights and barons bold, the stateliness of feudal castles, the solemnity of minsters, the pomp of tournaments, the peal of organs, and the dim religious light of painted windows. Such was the poet of Lycidas, of Comus, of the Allegro, and the Penseroso, the two most perfect gems of contemplative lyric poetry of which Britain has to boast; and yet we see these tastes abandoned or repressed as he advances in life and in party spirit, till at last he views them only as unnatural corruptions of primitive liberty and simplicity. Still, with Milton, though a taint of bigotry pervades his views, everything is pure, high minded, and disinterested. "Nought he does in hate, but all in honour." He stands at an immense distance from the sect to whom he had allied himself, but with whom, after all, he had little in common. In no one does poetry more conspicuously appear a part of religion. He regards it as a sacred trust, not to be sacrificed on the altar of vanity, not to be purchased for a price, not to be applied to any unworthy or even trifling end.

> Driving far off each thing of sin and guilt,
> And in clear dream and solemn vision
> Telling of things which no gross ear can hear;
> Till oft converse with heavenly habitants
> Begin to cast a beam on the outer shape,
> The unpolluted temple of the mind,
> And turn it by degrees to the soul's essence,
> Till all be made immortal.

It would be absurd, at the present day, to enter on any formal criticism of his great work of Paradise Lost, the most original, if not the most successful, of modern epics. About no poem perhaps are opinions more agreed; every one feels its sustained loftiness, combined with so much of tenderness, in the scenes of Eden, but always suggesting the idea of effort and labour,—the wonderful art with which learning itself is rendered poetical in his hands; for even the visions of mythology, and the fantastical traditions of chivalry, are made to heighten the effect of a sacred poem dealing with the mystery of the fall of man;—and, lastly, the consummate artifice of the versification, which, as Hazlitt remarks, seems to float up and down, as if on wings.

B[illegible]r.

Milton represents the more imposing side of the Puritans, and he is almost the solitary poet of whom they can boast. The other side of their character, their hypocrisy, and their narrow and coarse tastes, are exposed in the merciless and consummately clever Hudibras of Butler. The poem is now, no doubt, in a great measure obsolete, like every application of poetry to the exposure of the peculiarities or vices of a particular age; yet its masculine vigour, its condensation of thought, and its wit, entitle Butler to a very high rank among the broad humourists of poetry.

Dr[illegible]n,

From the oppressive wit and subtilty of Cowley and his fellows, it is delightful to turn to the manliness, the common sense, the "long-resounding march and energy divine," of Dryden, who marks the point of transition from the metaphysical poetry to the critical. He had himself in youth been strongly influenced by the pervading taste for conceit; and it must be admitted, that in the greater part of his dramatic writings this taint clings to him to the last. As a dramatist, indeed, we can admire in him nothing but the nerve and vigour of his dialogue, and that power of reasoning in verse in which he so much excelled. But in his other works, such as the Absalom and Achitophel, he threw aside this rage for conceits, he was natural, transparent, vigorous; his illustrations, instead of being sought for, as in the case of Cowley, on account of their remoteness and apparent inaptitude, are such as at once adorn and elucidate, and are felt to be close and familiar without being common. High imagination he did not possess, and for his purpose it was scarcely needed. He has, in fact, scarcely written a line which is pathetic, and few that can be considered sublime. Yet in fancy he was not deficient, for it supplies him with inexhaustible imagery; his Ode shows that he could be raised at times into a true lyrical enthusiasm, whilst his judgment rarely fails him, except, indeed, in those bombastic plays, which he had framed by jumbling together an imbroglio of two inconsistent models, the French school, from which he borrowed his rhymes and his affectation of sentiment; and the Spanish, to which he was indebted for the exaggeration of his passionate scenes, and the complexity of his plots. Had he known nothing of these, and been left to form himself on the model of Spenser and Milton and Shakspeare, and in a less artificial state of society, he might at least have avoided the gross want of nature evinced in these rhyming plays, though we can hardly persuade ourselves that, by any process of tuition, he could ever have become a great dramatist. "The general soundness and healthfulness of his mental constitution, his information of vast superficies though of small volume, his wit scarcely inferior to that of the most distinguished followers of Donne, his eloquence grave, deliberative, and commanding, could not save him from disgraceful failure as a rival of Shakspeare, but raised him far above the level of Boileau. His command of language was immense. With him died the secret of the old poetical diction of England, the art of producing rich effects by familiar words. In the following century it was as completely lost as the Gothic method of painting glass, and was but poorly supplied by the laborious and tesselated imitations of Mason and Gray. On the other hand, he was the first writer under whose skilful management the scientific vocabulary fell into natural and pleasing verse. In this department he succeeded as completely as his contemporary Gibbons succeeded in the similar enterprise of carving the most delicate flowers from heart of oak. The toughest and most knotty parts of language became ductile at his touch. His versification, in the same manner, while it gave the first model of that neatness and precision which the following generation esteemed so highly, exhibited at the same time the last examples of nobleness, freedom, variety of pause, and cadence."[1]

Pope.

Pope is the last great writer of that school of poetry, the poetry of the intellect, or rather of the intellect mingled with the fancy, which occupies the period from the Restoration to the close of the eighteenth century. In Dryden's satires and miscellaneous poems, we perceive the reasoning poetry brought to its perfection, as far as regards vigour of conception and force of expression. In these respects nothing remained to be added. But Pope possessed that quick tact and intuitive discernment, both of the range and limit of his own powers, and also of the taste of the age, which showed him the solitary direction in which, so far as regarded this philosophic and critical school of poetry, there yet remained an opening for himself. He felt that the qualities of his mind did not fit him to surpass, and scarcely to contend on equal terms, with Dryden, so far as regarded grasp or force; but he conceived, that in the way of polish, refinement, grace, and choice of expression, something yet remained to be done, and that that something he was able to afford. Selecting, by a natural preference, themes of a moral and didactic rather than passionate character, adopting the idea that everything should be polished to the highest pitch, and that artifice was the fundamental principle of poetry, that artifice, he thought, could hardly be carried too far; and, accordingly, with Pope we find habitual that attention to words which is only occasional with Dryden. If in Dryden we perceive a tendency to substitute logic and reflection for feeling, to exhibit pictures of conventional and artificial rather than of general nature, and to borrow his illustrations much oftener from science and art than from natural objects, this tendency appears still more decided and uniform in Pope, who is pre-eminently the poet of a period of high intellectual culture and limited poetical sensibilities; the poet who wrought to its last perfection the pure but limited vein which this contemplative and preceptive style of poetry afforded. After Dryden nothing new could have been achieved for this style of poetry, save what has been done by Pope; and what he attempted he perfected.

---

[1] Edinburgh Review

It is indeed impossible to award to him a rank in poetry of the same kind with that which had been occupied by our Miltons, Spensers, and Shakspeares. In the highest departments of poetry, the epic and dramatic, he has attempted nothing. In the lyrical he has failed. In translation his example has tended to corrupt the national taste, and to substitute a glittering, false, and metaphrastical version for a true translation. His forte is essentially the didactic and satirical; moral instruction or censure enforced with all the charms or all the point of which such subjects are susceptible. Within that range he has never yet found his equal; for to the logical and reasoning power and condensation of Dryden and of Boileau, he adds at times, as in his Rape of the Lock, an excursiveness and brilliancy of fancy, a compact strength with perfect harmony, a quiet, graceful, continuous humour, altogether without parallel. Yet, whilst speaking of the harmony of his versification, it must be added, that he carried this principle to excess; that his system of terminating the sense invariably with the line, and his pauses, placed almost always on the fourth or sixth syllable, led to a monotony the most painful when contrasted with the varied pauses and lines flowing into each other, which were so happily employed by our elder writers; and that, finally, in regard to rhymes, Pope, though he was singularly limited as to range, was even within that range far from correct.

Prior.

" The best," says an eminent critic, " of what we copied from the continental school, is copied in the lighter pieces of Prior. That tone of polite raillery, that airy, rapid, picturesque narrative, mixed up of wit and naiveté, that style, in short, of good conversation, concentrated into flowing and polished verses, was not within the vein of our native poets, and probably never would have been known among us, if we had been left to our own resources. It is lamentable that this, which alone was worth borrowing, is the only thing which has not been retained. The tales and little apologues of Prior are still the only examples of this style in our language."

As we advance through the eighteenth century, we perceive that the critical school of poetry had evidently attained its perfection in Pope, and was destined, at no distant period, to sink into mere prose, disguised under the appearance of verse. At least, after Pope, there is a visible decline, until the appearance of the first germs of a new taste, with which the intellect had less to do, whilst the feelings obtained a more decided supremacy.

Addison,
Swift.

Addison's poetry is so flat, and cold, and destitute of imagination, that, but for the exquisite grace and refined taste of his prose works, it would not now be mentioned; and Swift, though a most clever versifier, and endowed with no ordinary talents for libel in the shape of epigram or satire, can hardly, by any stretch of favour, be regarded as a poet.

Thomson.

The first symptoms of the change which had been gradually going on, appears in the return to a taste for simple instead of artificial nature; for as yet the revival of strong feeling or passion would have met with no sympathetic feeling on the part of the public. In Thomson are to be traced the first symptoms of the reviving taste for the " simple-natural." True it is, his field is limited. When he attempts narrative, when he indulges in properly didactic poetry, his style appears cumbrous, and his ideas commonplace enough. " Liberty," says Dr Johnson, " when it first appeared, I tried to read, and soon desisted." Few at the present day will even make the trial. But when he comes to deal with the matters which lie within his proper sphere, and are congenial to his quiet, contemplative, and indolent turn of mind, he is an original and a striking poet. We must never forget, in speaking of Thomson at the present day, that his poem was the first of its kind, and even yet, like Milton's Eve, it is the fairest of its daughters. Even now we must admire the painter-like skill with which, in his rural descriptions, he selects his point of view, the art with which he seizes the characteristic, and drops the less marking features of the landscape; the infinite variety of little circumstances connected with animate and inanimate nature, unnoticed by his predecessors, but which his quick tact detects and sets before our eyes; the soft, bland, Claude-like glow which he spreads over all he touches; the spirit of love, and benevolence, and philanthropy, which he awakens; qualities which give to his Seasons a fascination which, though felt most strongly in childhood, is yet not materially abated by the judgment of cooler years. His faults are cumbrousness of diction, and occasional vulgarity of taste.

Goldsmi

The same sweet and natural tastes, though of a more refined kind, the same philanthropical spirit, and the same gentle inspiration of poetry, are visible in Goldsmith. He has not indeed Thomson's sympathy with the sublime and terrible in nature; his mind habitually turned towards its milder and more smiling aspects, the fertility and richness of cultivation, the tranquillizing tone of village life, " the short and simple annals of the poor." " He is refined," says Mr Campbell, " without false delicacy, and correct without insipidity. Perhaps there is an intellectual composure in his manner, which may in some passages be said to approach to the reserved and prosaic; but he unbends from this grave strain of reflection to tenderness, and even to playfulness, with a peculiar grace, and connects extensive and philosophic views of the happiness and interests of society with pictures of life that touch the heart by their homeliness and familiarity....His whole manner has a still depth of feeling and reflection, which gives back the image of nature unruffled, and minutely. He has no redundant thoughts or false transports, but seems on every occasion to have weighed the impulse to which he surrendered himself; and whatever ardour or casual felicities he may have thus sacrificed, he gained a high degree of purity and self-possession."

Blair,
Ramsay.

The names of Blair and Ramsay deserve notice, the first as the author of a poem gloomy and homely, but with a decided character, and a picturesqueness of imagery, which redeem it from vulgarity, and which have been justly compared to the powerful expression of a countenance without regular beauty; the latter as the writer of a true pastoral drama, in a style totally different from the hackneyed mythological models on the subject, and delineating the natural and simple manners of the peasantry of Scotland, with a truth, a comic archness and tenderness, which entitle the Gentle Shepherd to an honourable rank in British poetry.

Savage,
Chatterton.

A mournful interest attaches itself to the names of Savage and Chatterton, both the victims of misfortunes caused, in some degree, by their irregularities of conduct or deficiency of principle. In the latter, in particular, the seeds of a mind of considerable power are evidently discernible, choked indeed with many rank weeds of evil tendency, but which, pruned and weeded by years and experience, might have rendered him an ornament to the literature of the eighteenth century.

Collins.

Collins wrote but little, yet that little was of first-rate merit. His Oriental Eclogues may be regarded as only a boyish production; but the rest of his lyrics suffer only by comparison with those of Milton, and that chiefly through a certain obscurity of diction, into which he was led by endeavouring to avoid the commonplaces of expression. In proportion to the neglect which they encountered on their first appearance, has been their popularity since. The Ode on the Passions, in particular, has become a universal favourite, by its admirable personations, the flush of beautiful colouring with which it is invested, and the richness of the versification, which adapts itself with such art to the themes of sadness and gaiety, or deep gloom, which alternate throughout the poem.

There is strength and nerve, but nothing more, in the ferocious satires of the dissipated Churchill; an undeniable, though very often turgid and unsubstantial, grandeur about Akenside's Pleasures of the Imagination; but there is also perfect truth in Johnson's remark, that the words are multiplied till the sense is hardly perceived, and that attention deserts the mind and settles on the ear. Some pleasing pictures in Dyer and Armstrong, and a natural grace in Shenstone (which, however, sometimes borders on childishness), will preserve a certain popularity to Grongar Hill, the Art of Preserving Health, and the School-Mistress. The merits of Falconer's Shipwreck have, we think, been overrated. Its technicalities frequently appear tedious, and few poets have dealt more in needless expletives and mere commonplaces of description. Of Glover, whose Leonidas was once compared to Milton's Paradise Lost, the world now remembers nothing except his clever ballad of Hozier's Ghost.

Young is a poet of more fire, and of a decided though perverted ingenuity. He exhibits a curious mixture of the style of Queen Anne's day with the more pensive and meditative cast of our own. Few poems could be pointed out in which so much point, rare wit, and brilliancy, have been employed with so little effect. The whole poem is a long epigram, a string of hyperboles. It is precisely such a work, indeed, as we should expect to be produced by a person naturally of a cheerful turn of mind, putting on, for the sake of effect, the garb of melancholy, and misanthropy, and weariness of existence; and composing, as he is said to have done, by the light of a candle stuck into a human skull. It has the worst points of Lord Byron's manner, without the earnestness and verity of that feeling of weariness of the world which speaks throughout Childe Harold.

Gray, in the delicacy, the classical neatness, and polish of his verses, is closely associated with the writers of the age of Anne. There is no doubt a certain want of ease and spontaneity about Gray; his inspiration seems to flow slowly; he rises with compulsion and laborious flight. His poetical fire seems often cold and phosphorescent; but he has a fine sensibility to the beautiful and sublime, a mind richly stored with the beauties of the classical and Italian poets, and he has combined his ideas of invention and recollection in a mosaic of singular delicacy and compactness.

In the Minstrel of Beattie, some of the features of modern poetry become discernible, in its stronger sympathy with nature; nay, even in the general idea of the poem, which describes the solitary growth of a romantic and poetical spirit, and which possesses high merits as a sweet picture of still life, and a vehicle of unobtrusive morality.

But the complete transition from the artificial style of the writers of Queen Anne, to that which characterized the poetry of the opening of the present century, first appears visible in Cowper; who, throwing aside the trammels of artificial refinement, and the imaginary requisites of a conventional poetical diction and classical imagery, ventured to write as he thought, with the force and freedom of an older and a better time. In no poet of the last century did a more vigorous and original cast of mind present itself; and to no poet are we more indebted for awakening that freer and more forcible spirit, that poetry of the heart rather than the head, which has formed the marking feature of our own times. His satirical and didactic poems, though abounding with wit, and animated by the eloquence of conviction, are indeed deformed by many defects, both of indifferent poetry and bigotry of opinion; but in his descriptive poetry, in his charming pictures of in-door life, his summer and winter landscapes (so different from Thomson's, by their minute detail), in those bursts of inspiration which occasionally escape the poet, as in that where he addresses the stars in the fifth book of the Task, he has left us some of the most touching and spirit-stirring passages of which the eighteenth century has to boast.

Burns. The same spirit appears, in Scotland, in the deep tenderness of the lyrics of Burns. Much of his poetry, doubtless, can only be remembered with regret, as the effusion of a reckless and ungoverned spirit, mistaking coarseness for force, and confounding genius with extravagance and irregularity. But he has left behind him a few strains which are of a higher mood, nay, of the very highest order; familiar and yet noble, tender and yet manly; such as a peasant only could have written, but a peasant who was one of nature's nobles. "Scotland," says an American critic, "owes a large debt of gratitude to Burns; for he invested the feelings and sentiments of its peasantry, their joys and sorrows, with dignity and beauty; he redeemed their language from neglect, if not from contempt; he made the heart of every true Scot burn within him as he thought of the hills and valleys of his native land; he first guided the footstep of the pilgrim to the scenes of her traditionary glories, and he sung those glories in strains so simple, yet sublime, that the world stood still to listen."

Although, in the poetry of Burns, there are abundant traces of that stern force and strong passion with which we have been of late rather too familiar, the general tone of the poetry of the eighteenth century may be described as quiet and contemplative. But the great and terrible events which darkened its close, exciting the minds of men throughout Europe, introduced into the literature of all nations a spirit of restlessness and doubt, a love of strong agitation and stimulus, which either manifested themselves in a longing retrospection and veneration for the past, or in wild discontent with the present, and delusive visions of the future. This tendency appears in the publication of our ancient ballads, and the enthusiastic admiration which their rough vigour, their simple pathos, and their spirit-stirring pictures of love or war awakened; in the undiscriminating republication and study of our older dramatists of the school of Shakspeare, and our lyrical poets of the period which immediately followed; in the popularity and influence which the works of Goethe and Schiller, stamped with the character of the time, immediately obtained, when introduced to us through the means of wretched translations; and in that mixture of scepticism, moody discontent, and wild enthusiasm which had been painted in such gloomy and forcible colours in the Werther, the Faust, and the Robbers.

On the poetry of the present century, however, we do not intend to enter at all. Many of its most distinguished writers are yet alive; and we are still too near to others to enable us to appreciate their merits with calmness or impartiality. We shall merely remark, that the leading directions which poetry has taken during that period seem reducible to three: The chivalrous poetry of Scott and his school, the taste for which has in a great measure disappeared; the gloomy and sceptical, but most forcible, and occasionally touching poetry of Byron, which may be said to have expired with the great original; and, lastly, the contemplative and philosophical poetry of Wordsworth, the better parts of which are animated by a natural tenderness, and sustained by a moral grandeur, of which the others cannot boast, and which, though its influence over the public mind has been more gradual, promises to maintain a more enduring popularity than either. Crabbe and Campbell alone seem to have been but little influenced by the genius either of Scott, Byron, or Wordsworth, and to have pursued an independent course. In the other poets of the nineteenth century, the influence of one or other of these master-minds, and sometimes of more than one, is too prominent and palpable to be mistaken. (W. W. W. W.)

POGGIO **Bracciolini**, a man of great parts and learning, who contributed much to the revival of letters in Europe, was born at the little town of Terranova, near Florence, in 1380. His first public employment was that of writer of the apostolic letters, which he held for ten years, after which he was made apostolic secretary, and in that capacity he officiated, under seven popes, for a period of forty years. In 1453, when he had attained the age of seventy-two, he accepted the employment of secretary to the republic of Florence, and he died in 1459. Poggio visited several countries, and searched many monasteries to recover ancient authors, numbers of which he brought to light. His own works consist of moral pieces, orations, letters, and a history of Florence from 1350 to 1455, which is the most considerable of them all. In 1802, the Rev. Dr Shepherd published, in one volume quarto, a Life of Poggio, containing much curious information in literary history.

POGGY **Islands**. See **Nassau Isles**.

POGROMNAIA RECA, a small river of Asiatic Russia, in the district of Nertschinsk. It has on its banks a spring of mineral water, which is successfully employed in the cure of several diseases.

POICTIERS. See **Poitiers**.

POINT, a term used in various arts.

Point, in *Grammar*, is a character used to mark the divisions of discourse. A point proper is what is otherwise called a *period* or *full stop*. See **Punctuation**.

Point, in *Geometry*, according to Euclid, is that which has neither parts nor magnitude.

Point, in *Music*, a mark or note anciently used to distinguish the tones or sounds. Hence we still call it *simple counterpoint*, when a note of the lower part answers exactly to that of the upper; and *figurative counterpoint* when any note is syncopated, so that one of the parts makes several notes or inflections of the voice, whilst the other holds on one.

A point is still used to raise the value of a note, and prolong its time by one half. Thus a point added to a semibreve, instead of two minims, makes it equal to three; and so of the other notes.

Point, in *Astronomy*, a term applied to certain points or places marked in the heavens, and which are distinguished by proper epithets.

The four grand points or divisions of the horizon, namely, the east, west, north, and south, are denominated the *cardinal points*.

The zenith and nadir are the *vertical points;* the points in which the orbits of the planets cut the plane of the ecliptic are called the *nodes;* the points in which the equator and ecliptic intersect are called the *equinoctial points;* that whence the sun ascends towards the north pole being called the *vernal point;* and that by which he descends to the south pole the *autumnal point*. The points of the ecliptic, where the sun's ascent above the equator, and descent below it, terminate, are called the *solstitial points;* the former being the *estival* or *summer point*, and the latter the *brumal* or *winter point*.

Point is also used to signify a cape or headland jutting out into the sea. Thus seamen say two points of land are in one another when they are in a right line against each other, so that the innermost is prevented from being seen by the outermost.

Point, in *Perspective*, is used for various poles or places, with regard to the perspective plane.

Point, in *Poetry*, denotes a lively brisk turn or conceit, usually found or expected at the close of an epigram.

Point-Blank, in *Gunnery*, denotes the shot of a gun levelled horizontally, without either elevating or depressing the muzzle of the piece.

POINT DE GALLE, a seaport and fortified town on the south-western point of Ceylon, reckoned the third in consequence in the island, whilst in point of trade it ranks next to Columbo. The petlah or native town is extensive, and enclosed with a wall, and the houses are superior to those at Trincomalee. It has a good and spacious harbour, especially the outer road; whilst the inner harbour is secure during a great part of the year, but the egress is not so easy, as it requires the wind from a particular quarter to carry the vessels out. During the season when the roadstead from Columbo is unsafe, ships frequently wait at Point de Galle till their cargoes are ready. The fortress stands very high, but is much out of repair; and not above six families reside in it constantly, except when the homeward-bound fleet is assembled there, when a much greater number is collected. There is no regular rainy season at Point de Galle; but being open to both monsoons, it has more rain than the continent of India. The shore, both to the westward and in the vicinity of the port, is lined with rocks; and it is therefore advisable to keep in twenty-five fathoms till near the entrance into the harbour. The exports are cinnamon, cardamums, arrack, oil, salt fish, and cotton. Fisheries are carried on to a considerable extent. Cinnamon is also grown, but not to such an extent as about Columbo. Near the fort is a colony of Chinese, established by government as gardeners for the purpose of raising vegetables, in which they have at length succeeded, and have also thriving plantations of sugar-cane. At Billegam, about twenty miles south-east from Point de Galle, is a celebrated Buddhist temple, in which is a recumbent figure of Buddha. There is also a gigantic four-handed figure of Vishnu, of a dark colour; and the walls are covered with painted figures of Buddha. In a corner is another figure seated on a cobra de capella snake coiled up, the hood of which forms a canopy over his head. Point de Galle was occupied by the Portuguese in 1517, and taken from them by the Dutch in 1640. It came into the possession of the British in 1796. It is sixty miles south from Columbo. Long. 80. 15. E. Lat. 6. N.

POINT GORDWAR, a low point of land which projects into the Bay of Bengal, at the mouth of the Godavery River. The sea breaks heavily over it. Long. 82. 17. E. Lat. 16. 48. N.

POINT PEDRO, a town on the northern extremity of the island of Ceylon. Long. 80. 25. E. Lat. 9. 52. N.

POINTING, in *Grammar*, the art of dividing a discourse by points into periods and members of periods, in order to show the proper pauses to be made in reading, and to facilitate the pronouncing and understanding thereof.

POINTS, in *Heraldry*, are the several parts of an escutcheon, denoting the local positions of any figure.

Points, in *Electricity*, are those acute terminations of bodies which facilitate the passage of the electrical fluid to or from such bodies.

POINTY, a town of Bengal, in the district of Mongier, delightfully situated on the south bank of the Ganges, in the view of the Rajemahl Hills, in a country abounding in game. Long. 87. 26. E. Lat. 25. 20. N.

POISON, any substance which, acting on living bodies in small quantities, occasions serious disturbance of their functions, and may cause death. The science which treats of poisons is termed toxicology.

Poisons have been known from remote antiquity; but the notions entertained of their effects were generally fanciful and vague, so that it is often impossible now to discover what the poisons of the ancients really were. In modern times a great addition has been made to our knowledge of them, both as regards their number and their action; and it is only within the last thirty years that the nature and the varieties of their action have been studied scientifically and with success.

The number of poisonous substances now known is very great, and there can be no doubt that very many still remain to be discovered, equally in the mineral, the animal, and the vegetable world, but more especially among vegetables. Numerous, however, as they are, they present many remarkable agreements in their effects or actions, so as to admit of convenient classification.

tion.

Some poisons produce no other effects besides what depend on the local injury they give rise to. Of these, some produce by their chemical properties absolute destruction of the textures to which they are applied; and the result depends less on the nature of the injury, than on the importance of the injured texture, and its sympathetic connection with other parts of the body. The mineral acids, such as sulphuric and nitric acid, and the mineral alkalis, potash or soda, are the best examples of this kind. Others, again, of those which act locally alone, produce inflammation, but not chemical destruction, where they are applied; and all the ordinary effects of inflammation may ensue; of which gamboge and colocynth are good illustrations. The action of the former description of local poisons does not differ essentially from that of mechanical injuries of the same textures; the action of the latter is almost identical with that of the natural causes of inflammation. A third description of local poisons merely produce a peculiar impression on the nerves of the part to which they are applied, without either destroying or inflaming its texture. But there is no pure instance of the kind yet known; all such poisons likewise act otherwise than locally. Opium and prussic acid are examples.

Other poisons, and these by far the most numerous, act upon remote organs and textures, on parts to which they are not, nay, cannot be, directly applied; and the effects of this kind are often developed without any appreciable signs of a direct local action. There is scarcely an important organ in the body which may not be brought thus under the influence of some poison or another. The brain is very often so affected, as by opium, belladonna, prussic acid, and charcoal fumes. The stomach and intestines are also frequently affected indirectly, as by arsenic. The spine is affected by nux-vomica, the kidneys and bladder by cantharides, the lungs by tartar-emetic, the heart by oxalic acid, the liver by manganese, the salivary organs by mercury, and many of the glands by iodine. Many poisons possess the property of acting on a great number of organs in this remote or indirect way, of which arsenic and mercury are perhaps the most remarkable instances. Arsenic introduced by the skin has been known to act on the stomach, intestines, kidneys, heart, the lining membrane of the eyes, nose, windpipe, and vagina, the nerves of voluntary motion, and the skin at a distance from its place of application. Physiologists are still in doubt through what channel these remote effects are produced,—some believing that the poison is carried in substance with the blood from the organ to which it is applied, into the parts on which it acts; others, that the operations are merely nervous, and consist of the transmission of certain local impressions along the nerves which communicate between one organ and another; and others, that both modes of action may exist, even for the same, and still more for different, poisons. Two facts, however, are clearly established, whatever theoretical deductions may be drawn from them; *first*, that very many poisons do enter the blood, and may be detected there; and, *secondly*, that these never enter except in very minute proportion, so that, unless very delicate tests are known for them, they may readily escape detection. It seems not improbable that some poisons are deposited by a species of election in particular organs; but of course their presence in the blood will give them access more or less almost everywhere, since there are few organs not traversed by blood-vessels, and minutely injected with blood.

The greater number of poisons produce their peculiar effects, through whatever texture they are introduced into the body. The effects of local poisons depend, as was stated already, on the texture to which they are applied; but the far more numerous denomination of poisons which act remotely, exert that action, to whatever part they are applied, provided they fairly enter the body. They enter the sound skin with extreme difficulty, unless in the form of gas or vapour, or with the aid of friction. But they act energetically through the surface of the true skin stripped of its cuticle, through the cellular texture under the skin, through the soft mucous membrane which lines the mouth, nose, ears, stomach, intestines, windpipe, and organs of generation, through the firm serous membranes which line the interior of the belly and chest, and also when introduced directly into the blood-vessels, more especially into the veins. They generally act with greatest energy when injected into the blood directly, or when introduced into the serous cavity of the chest or belly; but if they operate in very minute doses, their effects are scarcely less prompt when simply thrust into a fresh wound, or under the skin; and there is no way in which they exert their action with more swiftness and energy, than when inhaled into the lungs, provided they assume the form of gas or vapour. For the most part their activity is greatest when applied to organs and textures where absorption is most prompt.

The action of poisons is greatly modified by an infinite variety of collateral circumstances, without a thorough knowledge of which toxicology cannot be well understood, either as a branch of physiological science, or in its practical bearings on medical practice, as well as medical jurisprudence. These modifying circumstances cannot be accurately laid down here, but the most important are the following: quantity or dose, chemical or mechanical form, the texture directly acted on, habit, and peculiarity of constitution, either natural or induced by disease. By all of these causes the effects of poisons may not merely be altered in degree, but likewise even modified in kind, or entirely neutralized. 1. Most substances which are poisonous in moderate doses, are innocuous in small quantity; but some are amazingly energetic even in very minute quantities,—such as prussic acid or strychnia, the active principle of nux-vomica, either of which may prove fatal to a man in favourable circumstances in the dose of one grain,—or still more the poisonous secretion of venomous snakes, or the secretions of the human body in some diseased states, which will prove fatal in quantities inappreciably small if introduced into a wound. 2. As to mechanical form, poisons must be, or must become, either gaseous or liquid before they act; mixture and dilution weaken their activity, though there are exceptions to this rule; and some, which are rather insoluble, such as arsenic, are rendered nearly inert when mixed with insoluble powders of great tenuity, such as charcoal, magnesia, and the like. 3. Chemical changes materially affect their actions; corrosives becoming innocuous by neutralization, purely local irritants being thereby much enfeebled, and all of them being rendered more feeble, or even inert, if they are converted into substances insoluble in the secretions of the textures to which they are applied. Poisons that act through the blood on remote organs are little influenced by chemical changes, except in so far as their solubility is affected; a very important general principle, which ought never to be overlooked in the search for antidotes. Arsenic, mercury, prussic acid, opium, and numberless other poisons, are almost equally active in all their chemical combinations, provided they continue soluble. 4. The effect of the texture acted on in modifying the influence of poisons has been already adverted to. As examples of this, it may be mentioned that prussic acid has little or no effect through the sound skin, nor snake-poison when swallowed; and that strychnia, the active principle of nux-vomica, has no effect through the skin, while one or two grains might prove fatal if swallowed, and a third of a grain would probably kill a man in a few minutes if injected in a state of solution into a wound, into the cavity of the chest, or into a vein. 5. Habit weakens the effects of many poisons, as in the familiar instances of opium and ardent spirits, of which ten or twenty times what is sufficient to prove fatal in ordinary circumstances may be taken with impunity by those who have long used them. Mineral poisons are less under the influence of this modifying circumstance than vegetable poisons; and of the latter those are most influenced which act chiefly upon the brain. It is very difficult to account for the varying effect of habit on the energy of vegetable poisons. Strychnia, for example, the active principle of nux-vomica, seems altogether excluded from the modifying effect of habit; while another principle, analogous in elementary composition and in chemical properties, morphia, the active principle of opium, may through habit be taken without injury in a dose fifteen times as great as what might in ordinary cases prove fatal. 6. Peculiarity of constitution commonly operates in rendering the body more than usually sensible to the action of poisons, as in the case of opium, mercury, and cantharides, medicinal doses of which act with poisonous violence on some. In a few instances original peculiarity deadens the activity of certain poisons, and this is observed still more remarkably during the constitutional state of certain diseases, such as hydrophobia, locked jaw, mania, delirium tremens, and excessive loss of blood. In some constitutions substances not injurious to mankind generally produce all the phenomena of poisoning. Thus there is scarcely any article of food or drink, except the great staple commodities, beef, mutton, and the simple kinds of bread, which are not at times observed to act poisonously on some people. But the most remarkable substances of the kind are red fish, shell-fish, mushrooms, bitter almonds in small quantity, and eggs.

Classification.

It has been stated that poisons are exceedingly numerous, but that they possess only a limited number of actions. As these actions consist of derangement of the functions of certain organs and textures of the body, it follows that the outward signs of these derangements must be circumscribed within certain bounds, and that many poisons must agree with one another in producing the same, or nearly the same, outward signs. This general fact constitutes the basis of the most approved classification. Formerly physiologists endeavoured to arrange poisons according to certain theoretical notions of their nature, or according to certain mysterious properties imputed to them; and subsequently most were content with distributing them in three classes, according to the kingdom of nature whence they happen to be derived. Every classification, however, should have some practical bearing; and as the most important objects in the present instance are the decision of the question of poisoning in a general sense, the discovery of the particular poison, and the treatment of its effects, these points ought to be invariably kept in view. With this understanding, the best classification is obviously that which is founded on the external signs of poisoning, that is, the grouping of the symptoms produced by each. Such is the basis of all the most esteemed modern arrangements.

The whole wonderful multiplicity of poisons, when thus viewed, may be considered as either exciting irritation in particular organs, or disordering the functions of the brain and spinal marrow, or as uniting both these properties. The first are called *irritants*, the second *narcotics*, the third narcotico-irritants, or more usually *narcotico-acrids*. The irritants comprise chiefly the free acids and free alkalis, with many of their compound salts, several earths with their salts, many compounds of the metals, acrid vegetables, and acrid animal substances. These all agree in producing, as their principal phenomenon, destruction or inflammation, sometimes of the part to which they are applied, such as the skin, mouth, throat, intestines, and so forth,—and at other times of organs at a distance from their place of application, such as the stomach, intestines, kidneys, bladder, lungs. And the symptoms they produce are those incidental to inflammation generally, grouped, however, in so peculiar a manner, either in order, kind, or complexity, as in many instances to distinguish the cause which occasions them from any natural cause of inflammation. Many substances arranged among irritants produce effects which would also associate them with the class of narcotics; but still inflammation and irritation are their leading consequences. The narcotics comprise principally opium, prussic acid, the volatile oils of bitter almond, cherry-laurel, and other drupaceous plants; henbane, thorn-apple, deadly nightshade, and certain poisonous gases, such as carbonic acid, carbonic oxide, carburetted hydrogen, cyanogen, sulphuretted hydrogen. These agree in acting either upon the brain, or upon the spinal marrow, or upon both these parts of the nervous system at once. The symptoms thus arising are stupor and coma, delirium, convulsions, paralysis, with a great variety of less important yet often very significant phenomena. When coma is the chief result, the brain is considered to be chiefly acted on; when convulsions or paralysis occur without stupor or coma, the spinal marrow must alone suffer; and where both sets of phenomena present themselves, it is probable that the whole nervous system partakes more or less of the injury. The narcotico-acrids comprehend hemlock and other deleterious plants of the family Umbelliferæ, black and white hellebore, meadow-saffron, fox-glove, ipecacuan, nux-vomica, cocculus indicus, camphor, poisonous fungi, and all ethereal and alcoholic fluids, besides many others of less note, or not so familiar. It is difficult sometimes to separate the individuals of this class from the narcotics on the one hand and the irritants on the other. But for the most part they produce in different circumstances either narcotism or inflammation alone, or both conjunctly, and that either simultaneously or in succession.

Examples of their several kinds.

It may be well to illustrate these statements by a brief sketch of the effects of a few familiar or interesting species belonging to each class.

The purest examples of irritant poisons are the *strong mineral acids* and *alkalis*, namely, sulphuric, nitric, and muriatic acids, and potash and soda. These, when applied to the external parts of the body for a sufficient length of time, cause corrosion and consequent destruction; and life may be thus brought into imminent danger, either from the extent of the injury and the consequent sympathetic derangement of the vital functions, or from a variety of less direct or incidental disorders. Of such a course of things the public in this country have lately had too many illustrations, resulting from the execrable crime of throwing sulphuric acid over the person. When swallowed, the strong mineral acids and alkalis sometimes act in a great measure on the throat and gullet, more frequently on the stomach and intestines. In the former case there is instant and horrible sense of burning in the mouth, throat, and neck, eructation of acid matter, often bloody, or mixed with dark masses, excessive tenderness of the injured parts, incapability of swallowing, difficult, husky breathing; and the sufferer may either die suffocated, or from the depressing sympathetic impression produced on the heart; or he may survive for a length of time, perishing, however, miserably in the end, from stricture of the gullet and starvation, or he may recover after the discharge of more or less of the lining membrane of the throat, and a tedious and precarious convalescence. Where the stomach and intestines are acted on by the acids or alkalis, there is in general violent vomiting, often of blood, and, especially after swallowing anything burning pain in the pit of the stomach, extending over the belly, with excessive tenderness and eventually swelling, frequently profuse purging and gripes, and extraordinary prostration of the pulse and of the strength; and the issue may be either recovery, more or less prompt, or far more generally death, at times from the sympathetic depression of the heart and general system, more rarely from gradual exhaustion, occasioned partly by constant irritation, partly by inanition, on account of extensive injury of the internal membrane of the stomach,—on which digestion, probably, in a great measure depends for its integrity. These phenomena are purely the results of local corrosion and irritation. No remote phenomena arise except exhaustion of the heart, from sympathy with the local injury; in particular, there is no disturbance of the function of the brain, spine, or nerves, except what arises simply from exhaustion of the circulation. The most remarkable of all the irritants for subtilty and variety of action conjoined is *arsenic*. It is not, however, an absolutely pure irritant; for, though irritation of a multifarious nature is its most prominent result, it also disturbs the functions of the nervous system. When applied for some time to the surface of the body, denuded of the scarf-skin, it kills the part to some depth; at least a portion is thrown off by the process of sloughing, showing either that the part had been killed, or that inflammation is produced, of a kind which leads to its death. Both in this manner, and with much greater certainty if it is applied to a fresh wound, or introduced into any of the external openings of the body, or injected in solution into the cavity of the chest or belly, it excites irritation and inflammation, not merely where it touches, but likewise in various distant organs. The stomach and intestines suffer the most invariably, giving rise to violent vomiting, especially of all articles swallowed, burning pain in the bowels, tenderness, griping, purging, and excoriation of the anus. The kidneys, bladder, and organs of generation, are also often affected, causing strangury, suppression of urine, pains in the loins, tenderness in the lower belly, &c. The lining membrane of the air-passages likewise frequently partakes in the injury, as is indicated by hoarseness, cough, difficult breathing, expectoration, and deep-seated pain in the chest. Not unfrequently the investing membrane of the nostrils and mouth presents signs of derangement, such as redness, aphthæ, and constant discharge. These symptoms are also generally attended with extraordinary depression of the action of the heart, which is the most frequent cause of death; and this sometimes forms the only prominent effect, the sufferer dying in a few hours, with scarcely any other symptom but mortal faintness. Recovery may take place even though the complicated effects which have been described may have been developed. But after these primary disorders have disappeared, there are important secondary risks to be encountered, such as dropsy, gradual emaciation from constant disturbance of digestion, and, above all, epilepsy, palsy, and other affections characteristic of an action upon the nervous system. Of the symptoms thus indicating a narcotic action, the most pointed and most remarkable are epileptic convulsions and local partial palsy. To these illustrations of the phenomena of internal poisoning produced by the irritants, it may be well to add a short sketch of the very striking effects produced by many of them as external poisons, when they have been introduced into the substance of the skin or its subjacent cellular tissue, through a wound. Of poisons of the kind now alluded to the most familiar are *snake-poison*, and the *fluids of the dead human body* after certain diseases or in some peculiar unknown state; but similar effects are also produced by many acrid vegetables. The affection produced is diffuse inflammation of the cellular tissue, so called because it diffuses itself rapidly along that texture, without any tendency to become circumscribed, as in ordinary inflammation similarly seated. It is attended with some puffy elevation and tenderness of the skin over the inflamed part, but not always with redness—with pain, not always acute, usually of that kind called burning pain—and with excessive depression of the action of the heart; and death may ensue either in a few hours from the derangement of the function of the heart, or more slowly from extensive injury of the cellular tissue, which terminates in gangrene.

Of the phenomena produced by the narcotics, the purest and most familiar example is to be found in the effects of *opium*. This drug produces a great variety of interesting nervous phenomena when taken in small medicinal doses. When taken in a poisonous dose, it first occasions languor, giddiness, weakness, and drowsiness, afterwards deep sleep, attended in general with complete repose, soft, slow breathing, and highly contracted pupils, and then profound coma, or insensibility, which cannot be dispelled by any stimulants, and which usually proves fatal if it be permitted to be fully formed. In particular cases these symptoms are varied with delirium in the early stage, and convulsions in the advanced stage; but such deviations from the ordinary rule are rare. *Belladonna*, or *deadly nightshade*, is another narcotic which produces effects somewhat different. Its berries, which are sometimes eaten by mistake by children and other ignorant people, although they have a mawkish and by no means seductive taste, occasion in the first instance a singular state of very active delirium, in which the individual performs a series of incoherent and extravagant acts with much vivacity, or falls into the condition of somnambulism; and after some hours this is succeeded by a state of deep sopor or coma, as from opium, though more frequently intermingled with convulsions than in the case of that drug. Death is sometimes the result, and would be more frequent were it not that the precursory stage of active delirium often leads to the discovery of the offending cause, and its removal by fit treatment. *Prussic acid*, another pure narcotic, which is now almost as familiar as opium among poisons, rivals them all in subtilty and rapidity of action. Small animals, such as rabbits, have been killed with it in the brief space of four seconds. A single drop has killed a cat in half a minute, and one grain, or about four drops, has repeatedly proved fatal to man within three quarters of an hour. These statements apply to the pure acid, which is seldom seen; but the common acid of the shops, which is used in medicine, is equally energetic in larger doses; and so are the distilled waters and essential oils of the bitter almond, peach-kernels, cherry-laurel leaves, rowan-tree root, and apple-seeds, which all owe their poisonous qualities to the same cause. The effects produced by all these poisons are immediate, dreadful alarm, giddiness, and hurried breathing, speedily followed by convulsions, insensibility, one or two fits of deep convulsive respiration, and death. The *narcotic gases* act very much in the same manner with opium, as is well exemplified by the fumes of burning charcoal, and other forms of carbonic acid. When in a pure or concentrated state, carbonic acid extinguishes life immediately, in part by suffocation, on account of the exclusion of respirable air, and partly by its narcotic operation. But when breathed in a diluted state, as in an ill-ventilated mine, or in a confined chamber heated by charcoal, it induces giddiness, fulness of the features, ringing in the ears, gradually increasing stupor, and at length profound insensibility, commonly attended with lividity of the face, glistening of the eyes, and occasional convulsions, which often prove fatal, and always if not speedily relieved by fresh air and other suitable treatment.

The narcotico-acrids may be exemplified by a great variety of well-known and powerful poisons. *Hemlock*, which is believed to have been a familiar poison for more than two thousand years, but whose effects are very generally misunderstood, ought scarcely to be arranged in this class, where it is commonly placed. Its irritant properties are very ill defined. But it is a powerful and very remarkable narcotic, and its active principle, named *conia*, is scarcely inferior to prussic acid in celerity of operation, or in the smallness of its dose. It seems to act by paralyzing the muscles of voluntary motion and of respiration, without affecting the brain; and the symptoms are weakness of the limbs, gradually pervading the rest of the body, and terminating in loss of the power of motion, while at the same time the respiration, at first laborious, gradually becomes more and more circumscribed and slower, till at length it ceases, the heart all the while acting vigorously, and the sensation continuing unaffected. A better instance of a narcotico-acrid poison is *nux-vomica*, and its principle *strychnia*. These are counterparts in action to hemlock and conia. They powerfully stimulate the spinal marrow, producing violent convulsions, like those which attend locked jaw or tetanus, and without impairing the sensibility. The first symptoms are restlessness, undefinable uneasiness, and alarm, speedily followed by fits of stiffness of the jaw and neck, and then by violent paroxysms of muscular contraction, in which the limbs and arms are extended, the features hideously distorted, and the head, body, and legs bent backward forcibly; and the third or fourth fit commonly proves fatal. Strychnia, the source of these dreadful effects, is on a par with prussic acid and conia in energy; for a third of a grain will kill a wild boar in ten minutes, and one grain properly administered would certainly kill a man in half that time. So far this genus of poisons acts like the narcotics; but, in frequent instances, where the narcotic symptoms pass away, they are succeeded by the signs of inflammation in the stomach and intestines, namely, pain, vomiting, purging, and swelling of the belly, which affection, too, may prove fatal. Such irritant effects, however, are rare, perhaps because in the great majority of cases, death is brought about in the early stage by narcotism. A better example still of a narcotico-acrid is *fox-glove*. A most valuable and safe medicine in small doses, this plant nevertheless acts as a very dangerous poison in large doses; and it sometimes produces in the same case both deep coma with convulsions, and likewise profuse diarrhœa, with tormina and tenderness of the abdomen, while at the same time it occasions suppression of urine, and extreme depression of the action of the heart. By far the most characteristic illustrations, however, of the narcotico-acrid poisons are to be found in the *deleterious fungi*, or poisonous mushrooms as they are sometimes called. These differ from most other poisons in their effects being often put off (though to this rule exceptions exist) for several hours, apparently because time must be allowed for the digestion of substances on the whole difficult of digestion. The effects are singularly various; for it has been often observed, that among a number of persons who have partaken of the same poisonous stew, some had only giddiness, confusion, delirium, stupor, coma, and convulsions; while others suffered only from vomiting and purging, distension of the belly, tenderness, and griping; and a third party were seized at first with the former class of symptoms, and on these passing partially off, were attacked severely with the latter.

Besides the irritant, narcotic, and narcotico-acrid poisons, some writers on the subject admit a fourth class, under the name of *Morbid poisons*, comprising those poisonous secretions which are engendered in the body by disease, and possess the property of reproducing by contact or inoculation the same disease to which they owed their own production. The most important of these are hydrophobia, the venereal disease, small-pox, and cow-pox. Authors on toxicology, however, whether physiological or practical, have generally agreed of late in discarding these from the toxicological system, and in arranging the phenomena of their action where they are more philosophically placed, namely, among natural diseases.

In a work like the present, it is not easy to decide how much ought to be introduced of a subject so comprehensive as toxicology, or the science of poisons. The sketch given above will convey some idea of the objects of which it treats, more especially as a branch of physiology. Farther details on the subject at large seem uncalled for. But there are two departments which may be enlarged on with some advantage, namely, the Evidence of poisoning, and the Treatment of the effects of poisons. Poisoning, both criminal and accidental, has become so common and so notorious in recent times, that there are probably few persons who have not turned their thoughts to these two branches of the subject; and it is desirable for many reasons that correct views should be entertained of them, even by unprofessional persons,—more correct views, at least, than what generally prevail.

Evidence.

Till a very recent date, most erroneous notions were entertained, alike by the vulgar as by scientific men, of the evidence of poisoning. Proofs of the most unsubstantial kind were considered infallible tests of death by poison; and, under the authority of grievous professional error, we now know that courts of law must have sanctioned many a judicial murder. It is not uninteresting to trace these dogmas of antiquity, abandoned as they now are by the scientific, still obstinately adhered to by the unprofessional world as articles of popular belief, and leading, as of old, to constant blunders, which it is now the business and glory of the toxicologist to check, whilst it was formerly his fate to foster and give effect to them.

The evidence of poisoning cannot be thoroughly understood in all its bearings, without a minute knowledge of the multifarious phenomena produced by all ordinary poisons; and, in judicial cases, it is in the end viewed commonly in reference to the supposed administration of a particular substance. It would be out of place to attempt embracing this wide field here. All which can be ventured on is a view of the evidence of poisoning in a general sense, that is, without reference to any special poison,—a topic of great interest in relation to the first suspicions and earliest investigation of supposed cases of poisoning, whether criminal or accidental. The evidence of poisoning in this comprehensive sense is derived from symptoms, from appearances in the dead body, from experiments on animals, from certain moral circumstances, and from chemical analysis.

1. The *symptoms* are naturally the first particulars to attract attention and excite suspicion. They were once thought adequate to decide singly any question of poisoning. Now we know that natural diseases imitate so closely the phenomena of poisoning, that the symptoms will rarely yield more than presumptive, and only in rare and very peculiar circumstances, absolute evidence. There is nothing in the kind of symptoms taken generally which will distinguish poisoning from certain natural diseases. The natural diseases, indeed, which imitate the effects of one great class of poisons, namely, the irritants, are on the whole rare; yet they are scarcely less a source of fallacy, at least in judicial cases, where certainty, or something like it, must be aimed at. But there are a number of collateral circumstances connected with the symptoms, which, if taken together, will often supply a very powerful criterion in supposed cases. Thus, in the instance of by far the greater number of poisons, and of almost all which are used for a homicidal or suicidal purpose, the symptoms begin soon after food, drink, or medicine has been taken, commonly within an hour, often much sooner; and in respect of not a few common poisons, such as the mineral acids, mineral alkalis, hartshorn, prussic acid, oxalic acid, they must commence immediately. In general, too, the symptoms begin suddenly, advance quickly, and prove speedily fatal. For the most part they are steady in their progress, exclusive of the influence of treatment. They are upon the whole uniform in their nature. And they appear in the great majority of cases abruptly during a state of good health. The consideration of these characters will not unfrequently en-

able the man of experience to pronounce that suspicions which have prevailed of poisoning are wholly unfounded; but, taken singly, they will never justify, on the other hand, more than a presumption in favour of poisoning. It must at the same time be observed, that when these general characters are all applicable, and concur with a certain complicated grouping of the symptoms in particular cases, the presumption becomes very strong; and when other articles of general evidence are added, the proof may be all but complete, nay, absolutely so. Such is clearly the state of the case in not a few instances of poisoning with the mineral acids and alkalis, with arsenic, corrosive sublimate, nux-vomica, oxalic acid, prussic acid, alcoholic fluids. 2. The same confident reliance was long placed in the *appearances of the body after death*, as in the symptoms, and with even less reason. The discovery of certain morbid appearances may prove poisoning to have been impossible; and yet even here an opinion should not be formed without reserve, because the discovery of the effects of natural disease in the body, even in an advanced stage, is no absolute proof of death from that disease. Poison, as in many authentic cases, may have been nevertheless administered, and have proved the real occasion of death. But there is never anything in the appearances after death which will bear out a general charge of poisoning, as was once universally thought. It should be particularly known, that the vulgar prejudice, which discovers poison wherever the skin becomes unusually livid after death, or wherever the body undergoes prompt decomposition, is utterly without support from scientific experience. Nay, in regard to the latter character, evidence has been proved in recent times to be deducible from the very opposite condition, or the unusual preservation of the body from decay, which is now well known to occur in many cases of poisoning with arsenic. There are certain morbid appearances in the dead body, especially upon the skin, and in the throat, gullet, and stomach, which will furnish the strongest presumption, nay, according to good authorities, almost absolute proof, of poisoning with certain substances, for example the mineral acids; but the details cannot be entered upon here, because a full enumeration, and much professional skill, are required for appreciating precisely their import. 3. *Experiments on domestic animals*, made with suspected articles, were once supposed to furnish the best of all evidence; and this was probably the best evidence to be had in the days when chemistry and chemical analysis were all but unknown. Now, however, such experiments are not admitted, either by medical or legal authorities, to be of any weight, except under particular circumstances. They are admissible, and indeed clearly indispensable, for deciding questions in toxicological physiology which may arise during trials. They ought also to be allowed some weight when they have been observed accidentally, as, for example, when the remains of suspected articles have been devoured incidentally by domestic animals, especially by a number of them, and above all by the dog or cat, with the effect of producing in them symptoms and appearances after death similar to what were witnessed in the suspected case in the human subject. The objection drawn against such evidence, that the effects of many poisons on the brute creation are different from their effects on man, though fundamentally sound, has been allowed to operate far too sweepingly in modern times. The differences in respect to many common poisons are by no means so great as was thought not very long ago; and upon two animals, the dog and the cat, the effects of most poisons are almost identical with those observed in man, due attention being paid to differences in dose, and to the singular facility with which these animals discharge poisons by powerful early vomiting. But the objection here stated may be allowed sufficient force to put an end to experiments made expressly on animals with suspected articles. There is, however, a more urgent objection to such experiments,—that they involve the consumption for doubtful evidence of the materials from which decisive evidence may be obtained by other means; for if there is poison enough left to affect sensibly the lower animals, there is amply sufficient for detection by chemical analysis. Accordingly, express experiments with remains of suspected food, drink, or medicine, are now abandoned by all good authorities in toxicology. 4. There are certain *moral circumstances* which may also be often taken into account in the evidence of poisoning in a general sense, when viewed as a scientific question, because they cannot be correctly appreciated except by a scientific man, and consequently they belong in some measure to the scientific or toxicological proof. The chief particulars are as follows. It may be proved that poison has been purchased, of a kind which may produce the symptoms observed. A suspicious article may be proved to have been administered, either from its taste, or from its having been recommended for properties either absurd in nature, or such as the pretended article is not thought even by unprofessional people to possess, or from a comparative analysis of the materials for making the suspected article, showing that something injurious must have been added at a particular time, and by a particular person. It may be proved that exacerbations of the symptoms have repeatedly occurred soon after articles were given in a suspicious manner. It may be proved that the person poisoned, or a second party under suspicion, exhibited by words or deeds an intention to administer poison, as by assigning impossible properties to what is administered, or by manifestly changing medicine which has been prescribed. A highly important circumstance is the simultaneous and similar illness of several individuals who have partaken of the same meal, coupled perhaps with the degree of their illnesses concurring with their respective shares, and probably also united with the escape of others of the same company who did not partake of the meal, or of particular dishes or liquors. Many other moral circumstances might be here alluded to, by which the question of poisoning in a general sense may be often materially cleared; but as they do not belong to the scientific view of the question, either directly or indirectly, they may be passed over. 5. The *chemical evidence* is justly considered the best of all the departments of proof; for it not only establishes poisoning in a general sense, but likewise points out the particular poison. There is no department of toxicology which has made such amazing progress in recent times as that of toxicological analysis. A century ago, the search for the remains of poison in suspected dishes, or in the dead body, was scarcely ever attempted, and, owing to the ignorance of the chemical properties of poisons, could not have been successful. Even no more than five-and-twenty years ago, the method of analysis was in all cases crude and unsatisfactory, and for many poisons good processes continued unknown; so that it was no uncommon thing for charges of poisoning to break down, solely on account of the dubious quality of the chemical evidence. But at present, the proof of poisoning is scarcely ever defective in the chemical branch; the evidence of death by poison is usually complete; and how can it fail to be so in competent hands, when the chemist can detect in the most complex mixtures the minute quantity of a twentieth or fiftieth of a grain of the common poisons, and when many years of interment frequently cannot withdraw the crime of the poisoner from the keenness of his search? It has been proved by careful experiments, that the mineral acids, arsenic, corrosive sublimate, blue vitriol, opium and its principle morphia, strychnia the principle of nux-vomica, cantharides, and other less familiar substances, may be discovered in the body of animals poisoned with them, though buried for nine months; and instances have occurred of the detection of arsenic in man after interment for two, four, and even seven years. It does not absolutely follow that death has been occasioned by poison because poison is found within the body after death; for it may have been feloniously introduced afterwards, for the purpose of falsely imputing poison; or, though poison has been swallowed, death may nevertheless have arisen either from natural disease, or some other kind of violence. Instances of such extraordinary occurrences are absolutely not uncommon, sufficiently so at least to require being kept always in view. The determination of them involves too refined an inquiry to be considered here. On the other hand, the non-discovery of poison after death is still farther from being evidence that death was not occasioned by poison. For many poisons are still undiscoverable by any method of analysis; others are soon decomposed within the body after death, such as prussic acid; others are quickly absorbed from the stomach during life, so as to prove fatal without leaving any remains behind, as in many instances of poisoning with opium; others may be expelled by vomiting, and nevertheless have, in the first instance, occasioned injury enough to prove fatal, as sometimes happens in the case of arsenic, and very commonly in poisoning with mineral acids. It has, however, been made a subject of question, whether the evidence of poisoning can ever be considered as complete, so as to involve a conviction in a criminal case, unless poison be found either in the body or in the remains of a suspected article which has been swallowed. It appears absurd, however, to insist on the absolute necessity of such evidence. For were the poisoner to choose his means skilfully, and avoid over-doses, he would, on such principles, almost constantly escape. And the best scientific authorities, in the most recent times, seem inclined to allow that the general evidence, from the various sources detailed above, may be often so strong as to leave scarcely any scientific doubt of the occurrence of poisoning; and the conjunction of the circumstances of ordinary evidence may, in a legal sense, entirely remove what little doubt may have existed of a scientific nature. Accordingly there have been instances of condemnation lately in this and other countries, where poison could not be discovered. It may be right to add, that it is most singular how effectually and how quickly poisons are sometimes removed beyond the reach of analysis by incidental causes, even those poisons which may be detected in other circumstances in extremely minute quantities, and where the methods of analysis are well understood. Prussic acid is seldom to be detected if life be prolonged for half an hour, while in the ordinary cases of death in a few minutes it may be discovered with ease. Arsenic, which in the great majority of cases adheres obstinately to the stomach, and may in consequence be detected there though life has been prolonged under frequent vomiting for two days and upwards, has been known to be removed beyond the reach of analysis in the short space of five hours.

Treatment.

The *treatment* of poisoning, like all other branches of toxicology, has, within a few years, been prodigiously improved. It may be said, indeed, to have been understood only within the last quarter of a century. In ancient times the notions entertained of the treatment were not less crude than those formed of the nature and action of poisons. Among other errors, it was strangely supposed that certain counter-poisons existed, which not only possessed the property of curing the effects of all poisons indifferently, but which likewise, when taken for a length of time, had the faculty of impregnating the constitution, and rendering it proof against the influence of any poison. Princes and others often lived thus for years under the care of their physicians, or protected against their treachery, by being charged with conservative antidotes. After these notions were exploded, other erroneous practices came into vogue; and, in particular, it was believed to be established on the basis of observation, that certain antidotes, such as vinegar, milk, oils, and the like, which are really not amiss in some forms of poisoning, were equally efficacious in all. These illusions have been dispelled, even among professional people, only within a very few years; and among the unprofessional they still have currency. The clearing away of the mists of error has been attended with the discovery of many real and most valuable remedies. The improvement which has taken place has been owing partly to the improvements made in chemistry; but in this way nothing could have been ultimately effected without the aid of physiological experiment, and more especially of experiments on animals, a method of inquiry, nevertheless, which it has been too much the practice of an ignorant or spurious humanity to decry.

The treatment of poisoning is directed to three objects, the removal of the poison, the administration of an antidote, and the cure of the disorders which have been produced.

1. The first object, in every instance, is the prompt removal of what may remain of the poison. If it had been applied outwardly to a sore or wound, it must be carefully wiped or washed away. When introduced deep into or under the skin by a puncture, it is to be withdrawn by suction with the mouth, and, still better, with a cupping-glass, the efficacy of which is insured, as in the case of snake-poison, by a bandage being applied above the wound, so as to obstruct the return of blood from the veins to the heart, but without compressing the arteries. Another plan, which has been found effectual in the like circumstances, is simply to apply the bandage above the wound, and then to open a vein between the wound and bandage, so that the poison is drawn from the wound with the blood, and discharged outwardly from the orifice in the vein. Sometimes it is useful to make deep scarifications before applying the cupping-glass; yet in this way the bottom of the wound may be missed; and, on the whole, if incisions are to be made at all, it seems better to calculate the probable depth of the wound, and to remove a portion of the texture with the knife all around it. The bleeding which follows commonly effects the discharge of the remaining poison; but some afterwards add the use of an incandescent iron for cauterizing the whole adjacent parts. The removal of the poison, when taken internally, may be variously managed. But, first, care must be taken not to attempt its removal when nature may have already looked after this step in the treatment, as in the case of profuse, and frequent, and full vomiting. All that is necessary in such circumstances, is to give occasional draughts of lukewarm water, or milk and water, to render vomiting easy, and to aid in washing out the stomach. When vomiting does not occur, or is not free, an emetic ought to be promptly given. Whatever is nearest should be first tried, mustard, for example; but the most effectual is white vitriol, in the quantity of a scruple or half a drachm, dissolved in a large wine-glass-full of water, to be repeated in fifteen minutes if necessary. Where the symptoms indicate narcotic poisoning,—for instance, with opium,—it is essential to keep the person roused after giving the emetic, otherwise it will hardly act. Emetics, when they do operate, are greatly preferable to the stomach-pump, which has been of late currently substituted for them. The stomach-pump, however, is one of the most important additions which have been made to the healing art in modern times. In very many instances of narcotic poisoning no emetics will operate; and all such cases, till of late, inevitably perished where the quantity of poison was considerable. The stomach-pump insures the prompt removal of almost all poisons; so that when used in time recovery is next to certain, where formerly a large majority of cases proved fatal. 2. By all such means, however, the poison

is often but partially removed. Some of it pervades the system; more of it impregnates the tissues with which it was in contact, and is ready for absorption; much of it often passes down into the intestines; occasionally it adheres with obstinacy to the inner membrane of the stomach, and cannot be dislodged either by emetics or by washing through means of the stomach-pump. The second object, then, is to administer an antidote. Antidotes have usually been conceived to be of two kinds. Some, by changing the chemical form of poisons, render them inert, and are called chemical antidotes. Others are thought to subdue the morbid action of poisons by exciting a counter-action, and are termed constitutional antidotes. In ancient times, and likewise until the recent improvements in toxicology, scarcely any other antidotes were known, except what belonged to the constitutional class. But it is now thought that in correct language scarcely any such antidote exists. European physiologists are not acquainted with any decided constitutional antidote for any of the numberless multitude and variety of poisons now familiar to the scientific. It is very generally believed, however, that savages in all quarters of the world are in possession of remedies of this nature, more especially for the effects of snake-poison. Apparently authentic accounts have been published, of a considerable variety of antidotes known to the natives in different parts of North and South America for the bite of venomous snakes. But none of these supposed antidotes have been found to stand the test of scientific investigation; natives who put trust in them have been seen to perish in the usual way; there is no difficulty in accounting for their apparent occasional success; and those who give faith to the marvels of travellers on the subject ought to consider how very extraordinary it would be, if, in every part of the globe where there are savages, discoveries of this kind should be made in regard to their poisons, while, with all the advantages of science to aid them in the search, no civilized people have yet contrived to stumble on a similar discovery in relation to any of the innumerable poisons with which they have long been familiar. If constitutional antidotes are still much wanted, there is no want of excellent antidotes of the chemical class. Some of these act by neutralizing the chemical qualities on which the properties of the poison depend, others by simply rendering the poison insoluble. Thus sulphuric acid is rendered inert by magnesia, because it becomes thereby a neutral salt, soluble, indeed, but no longer capable of corroding the animal textures, or of exciting violent irritation. In like manner potash is rendered inert, or nearly so, by lemon-juice or vinegar, or, though less easily, by oil, because it is converted into neutral salts, which are feebly irritant and not at all corrosive. On the other hand, oxalic acid is rendered inert by magnesia, partly because its corrosive qualities are neutralized by chemical neutralization, but chiefly because these, in common with its not less formidable effects on the nervous system through absorption, are prevented by a substance resulting which is insoluble. So, too, arsenic becomes inert when brought thoroughly in contact with the hydrated peroxide of iron, because an insoluble compound is formed, the arseniate of iron. In using and searching for antidotes of the chemical kind, several important general rules should be attended to. For, first, where a poison is a pure local irritant, destitute of action through the blood or remote organs, it is usually sufficient that it be neutralized; because the resulting compound is commonly but a feeble irritant, although soluble. One condition, however, must be observed, namely, that the antidote shall be itself innocuous, otherwise harm may be done by the antidote before it comes in contact with the poison, or because it is given in excess. Thus the mineral acids are unfit antidotes for neutralizing the mineral alkalis, and the latter for neutralizing the former. But, secondly, when the poison is of a kind which acts on remote organs through the medium of absorption, it is not enough that it be chemically neutralized. For all such poisons act as such throughout their soluble compounds; their compounds act on the whole in proportion to their solubility; and those only are inert which are insoluble, and insoluble not merely in water, but likewise in the animal fluids of the stomach. Hence oxalic acid and arsenious acid (common arsenic) are not neutralized in their physiological actions by being neutralized with potash; prussic acid similarly treated remains as energetic as ever; and the powerful vegetable alkaloids, morphia, strychnia, conia, and the like, instead of becoming inert by neutralization with acids, are rendered positively more active, because they are made more soluble. In the case of every poison, then, it is advantageous, and in very many it is indispensable, that the chemical change effected shall be such as to impart to the compound insolubility; and care should be taken that this insolubility shall exist in regard to the natural juices of the stomach, which are commonly acidulous. But, thirdly, the antidotal tendency of such chemical remedies, even when of undoubted virtue, is often counteracted where the poison is a fine rather insoluble powder; for it adheres forcibly to the inner coat of the stomach, irritates it to throw out tough mucus, which covers the powder, and defends it against the approach of the neutralizing agent. Frequent instances of such a course of things occur in the case of poisoning with arsenic. 3. The last object of the treatment of poisoning is the cure of the disorders which the poison has produced. These disorders, since they are substantially natural diseases, must be treated as such. But there are certain circumstances which render them in some measure peculiar, and consequently modify the treatment. These are chiefly as follows. Treatment will obviously be of little use for such disorders, until what remains of the poison be removed or rendered inert; and as this object is often unattainable, ultimate success is frequently beyond reach. Evacuation of the poison is in this point of view of primary importance, as well as for its own sake. In the case of poisoning with the irritants, the treatment is often exceedingly embarrassing, because it must be simultaneously directed towards two opposite ends, the suppression of inflammation by evacuating, and consequently debilitating measures, and the removal of depression of the heart and general system by stimulating remedies. These two contrary and incompatible objects are often the cause why the best treatment proves inefficacious. The treatment of narcotic poisoning is somewhat differently circumstanced. The remains of the poison being removed, there is only the induced disorder to combat. These disorders are in the great majority of cases functional only; that is, no structural injury has been occasioned. Hence, the offending cause having been withdrawn, there may be expected to prevail in the constitution a natural tendency to throw off the functional disorder,—a tendency towards recovery. Experience shows that such is actually the fact. If in narcotic poisoning the remains of the poison can be removed, and life can be preserved for a moderate length of time, success is highly probable in a great majority of cases. Thus very few die of poisoning with opium, and perhaps still fewer ought to die in skilful hands, who survive for eighteen hours. In narcotic poisoning, then, the treatment for subduing the disorders induced consists mainly in employing, in some instances, sedatives for subduing irritation of the nervous system, but much more commonly stimulants, for the purpose of keeping the person roused, and in applying various means for supporting artificial respiration where the natural breathing fails. Excellent methods for accomplishing the first object are now in familiar use, such as loud talking, agitation of the body, injecting water into the ears, tickling the nostrils, dashing cold water over the head and shoulders, applying sinapisms to the calves, blistering the head with boiling water, and internally ammonia, ether, and spirits. But the best method of supporting artificial respiration has not yet been discovered; there are practical objections to all the methods yet devised; and it is only when these shall be perfected, that the treatment of narcotic poisoning will be rendered substantially superior to what it is at present. It is not unlikely that galvanism will be found a material part of the most efficacious method,—applied, however, not continuously, as is often practised, but interruptedly, so as not to disturb the alternate contractions and relaxations of the respiratory muscles.

Action on vegetables.

In the preceding observations on the effects and treatment of poisoning, poisons have been regarded solely in their operation on the animal body. But they were defined at the outset as acting on living bodies generally; and upon vegetables their action is not less remarkable than upon animals. This branch of the subject has been hitherto little studied; but what is already known of it seems full of interest both in a physiological and in a practical point of view. It appears that in a general sense there is a close analogy between the actions exerted by poisons on both divisions of the living world. As there are two leading effects produced in animals, so are there two great classes of phenomena developed in vegetables, those of irritation and those of narcotism, or at least of an action closely analogous. The apparent phenomena of both kinds are indeed much simpler in vegetable than in animal beings, partly because the organs and functions of the former are more simple than those of the latter, partly because physiologists have not yet ascertained with precision the special changes that are induced. Still, however, it is easy to trace in vegetables the leading effects produced by irritants and by narcotics respectively, upon animals. The former occasion partial or general disorganization or death of the organs of plants to which they are directly applied, and the plant may eventually either recover or perish, according to the extent of the injury or the importance of the organ injured. The latter seem to act upon the vitality of the plant, without in general producing any marked change of a local nature, or such as may be referred to a direct impression, at least until the first signs of vital depression appear; and it is commonly observed, that so soon as such signs of depression do make their appearance, however slight they may be, they quickly pervade the whole plant, which in consequence perishes irrevocably. The irritants appear to act topically, and from without inwards; the narcotics act more generally, and from within outwards, being probably first absorbed.

Poisons act upon vegetables, through whatever channel they are introduced, and to whatever organ they are applied, provided the texture be such as to admit of their passage to those parts which are more or less directly connected with life. The organs through which they act with greatest energy are the leaves and the roots. Liquid poisons act with most energy through the roots; gaseous poisons are probably most energetic when applied to the leaves. Partial action is sometimes produced by the topical application of a general or narcotic poison; thus arsenic introduced into the axilla of a leaf of the *dipsacus fullonum* kills the whole superior part of the plant on the side corresponding with the leaf. Vegetable poisons are not less energetic than mineral poisons. Nay, however extraordinary it may appear, there seems no question that plants may be promptly killed by their own poisons,—that the poison produced by a particular species may kill that species as readily as it will others, if applied to the root so as to be absorbed into the nutritive juices. This singular phenomenon may depend on the poison being secreted and confined in particular receptacles in the ordinary state of the plant. But another and more intelligible explanation in regard to certain poisons may be drawn from the well-ascertained fact, that some vegetable poisons, and probably more of them than the physiologist may at present be inclined to admit, do not exist ready formed in the plants whence they are obtained, but are produced only when certain principles, existing naturally apart in distinct receptacles, are brought in contact by mechanical force or chemical manipulations. A remarkable instance in point is the essential oil of the bitter-almond kernel, or cherry-laurel leaf, which does not exist ready formed, otherwise it would be betrayed, like other essential oils, by its powerful odour, but is formed only when certain principles, named *amygdalin* and *emulsin*, are brought in contact with each other and with water.

No poisons are better fitted for illustrating the phenomena of poisoning in vegetables, or better deserve the attention of physiologists and practical men, than those which are gaseous in their nature. Most of them seem to act in excessively minute quantities and proportions. A tenth part of a cubic inch of muriatic acid gas, which is equivalent to the twenty-fifth part of a grain by weight, will in no long time destroy a small plant, although the gas be diluted with twenty thousand times its volume of air; and the devastating effects produced on surrounding vegetation by all manufactories where this acid is thrown abundantly into the atmosphere, as in the manufacture of black-ash and soda from sea-salt, abundantly show that far less proportions will prove equally deleterious when applied continuously. Sulphurous acid gas acts with nearly as great intensity. The effect of either of these poisons is simply to shrivel and wither the leaves and buds, like the action of frost in spring; and the plant will eventually recover if removed in time from the influence of the noxious agent, but with the loss of its foliage. Other gases, such as sulphuretted hydrogen and cyanogen, produce no visible change until the leaves begin to bend and droop; after which the drooping quickly extends, till at length the whole plant becomes flaccid, so as to present exactly the same appearance as when deprived of moisture; and it perishes inevitably.

Some substances which are poisonous to animals are not poisonous to vegetables. The experiments which have been made on this subject are neither sufficiently extensive nor sufficiently exact to warrant any general deductions. A very remarkable instance is carbonic acid gas, a small proportion of which in the atmosphere will speedily extinguish animal life, but which is innocuous to vegetables in almost any proportion, nay, on the contrary, is commonly thought to supply them with aliment.

Uses.

Poisons are by no means without their uses in the economy of nature. It is in the first place not improbable that vegetable poisons serve some purpose in the economy of the plants which produce them. On this point we are still much in the dark, in consequence of the little advancement which has been hitherto made in vegetable physiology. But one purpose of the kind seems to be the perpetuation and extension of such plants, by rendering them unfit for the food of herbivorous animals and frugivorous birds, which by instinct commonly avoid them. In the case of certain poisons of the animal kingdom, their purpose is obviously to preserve the animals which are endowed with them, by enabling them to destroy their prey and their enemies. Another important use to which poisons from every kingdom may be applied, is for the treatment of diseases. A very close connection subsists between medicinal and poisonous action. This is sufficiently shown perhaps by the undoubted fact, that, with very few exceptions, our best medicines are active poisons; and, conversely, that there are few active poisons which have not been turned to account as useful medicines. Besides, in the greater number of instances, the two properties, medicinal virtue and poisonous influence, are plainly nothing else than manifestations of the same action, differing merely somewhat in degree, which is well exemplified by most purgatives and emetics, by opium, henbane, prussic acid, and other anodynes, and by counter-irritants, or substances employed for irritating the skin. In other instances, again, where the poisonous and medicinal actions are to appearance different and unconnected, the existence of some relationship between them seems to be pointed out by the activity of the substances as drugs being proportioned to their energy as poisons. Another purpose to which some poisons are applied is for the destruction of the lower animals for the use of man. In most parts of the world, where the primitive habits of mankind have not been materially modified by civilization, poisons of great energy are familiarly employed for the destruction of game, and in some countries also for killing beasts and birds of prey. In civilized countries they have hitherto been used chiefly for the more ignoble purpose of getting rid of vermin. But they are susceptible of far more important applications of the same nature; which, however, have been as yet entirely overlooked. (x. x. x. x.)

Poison-Tree of Java, called in the Malayan language *Bohun Upas*, is a tree which has often been described by naturalists; but its existence has been very generally doubted, and the descriptions given of it, containing much of the marvellous, have been treated as idle fictions. M. Foersch, however, in an account of it, written in Dutch, asserts that it does exist, that he made the most particular inquiries, and that he found it was situated in the island of Java, about twenty-seven leagues from Batavia. The poison procured from the Upas is said to be a gum, issuing from between the bark and the tree, and brought by malefactors who have been condemned to death.

But a variety of circumstances conspire to prove that Foersch's account of the tree is extremely suspicious. Although he had letters of introduction, he went to no considerable house, and afterwards withdrew amongst the English. The distances given to mark the situation of the tree are not accurate. The execution of criminals is different from what he represents. There were no such disturbances in 1775 as those stated by Foersch, the tract to which he alludes having submitted to the Dutch East India Company as early as 1756. And, lastly, the assertions and pretended facts of Foersch are supported by no collateral evidence. Sir George Staunton, during his stay at Batavia, made the most particular inquiries concerning the Upas, but found that the existence of such a tree had never been known there.[1]

POITIERS, an arrondissement of the department of the Vienne, in France. It extends over 792 square miles, and comprehends ten cantons, divided into 101 communes, and containing 88,600 inhabitants. The capital is the city of the same name, the seat of the departmental government and of the courts of law. It is an elevated spot, almost surrounded by lofty rocks, at the foot of which run the river Elain on the east side, and the river Boivre on the west; both of which streams unite to the north of the city. It is surrounded with ancient walls, and is built in an antique style and irregular manner. It is the see of a bishop, and has an old cathedral and several other churches, three hospitals, an academy, a lyceum, a public library, 4160 houses, and about 19,500 inhabitants. It is a place of little commerce, chiefly confined to making a few woollen cloths, some hosiery, leather, and distilling brandy. Near to it are some Celtic and some Roman antiquities. It is celebrated for the battle which bears the name of the city, though fought at Beauvoir, between Edward the Black Prince of England, and King John of France, in the year 1356, when the latter was made prisoner. ---

[1] In the Edinburgh Philosophical Journal (vol. xii. p. 102) we find the following account of a visit to the Valley of Death, extracted from a journal of a tour through the islands of Java and Madara, by Mr A. Loudon, in the year 1830.

"*Balor, 3d July* 1830.—This evening, while walking round the village with the Patteh (native chief), he told me that there was a valley only three miles from Balor, that no person could approach without forfeiting their lives, and that the skeletons of human beings, and all sorts of beasts and birds, covered the bottom of the valley. I mentioned this to the commandant, Mr Van Spreewenberg, and proposed that we should go to see it. Mr Daendels, the assistant-resident, agreed to go with us. At this time I did not believe all that the Javanese chief told me. I knew there was a lake close to this, and that it was dangerous to approach too near, but I had never heard of the Valley of Death.

"*Balor, 4th July.*—Early this morning we made an excursion to the extraordinary valley called by the natives *Guwo Upas*, or Poisoned Valley; it is three miles from Balor, on the road to the Djienz. Mr Daendels had ordered a footpath to be made from the main road to the valley. We took with us two dogs and some fowls, to try experiments in this poisonous hollow. On arriving at the foot of the mountain, we dismounted and scrambled up the side, about a quarter of a mile, holding on by the branches of trees; and we were a good deal fatigued before we got up the path, being very steep and slippery from the fall of rain during the night. When within a few yards of the valley, we experienced a strong, nauseous, suffocating smell; but on coming close to its edge, this disagreeable smell left us. We were now all lost in astonishment at the awful scene before us. The valley appeared to be about half a mile in circumference, oval, and the depth from thirty to thirty-five feet; the bottom quite flat; no vegetation; some very large (in appearance) river-stones; and the whole covered with the skeletons of human beings, tigers, pigs, deer, peacocks, and all sorts of birds. We could not perceive any vapour or any opening in the ground, which last appeared to us to be of a hard sandy substance. It was now proposed by one of the party to enter the valley; but at the spot where we were this was difficult, at least for me, as one false step would have brought us to eternity, seeing no assistance could be given. We lighted our cigars, and with the assistance of a bamboo, we went down within eighteen feet of the bottom. Here we did not experience any difficulty in breathing, but an offensive, nauseous smell annoyed us. We now fastened a dog to the end of a bamboo, eighteen feet long, and sent him in; we had our watches in our hands, and in fourteen seconds he fell on his back, did not move his limbs or look round, but continued to breathe eighteen minutes. We then sent in another, or rather he got loose from the bamboo, and walked in to where the other dog was lying; he then stood quite still, and in ten seconds he fell on his face, and never afterwards moved his limbs; he continued to breathe for seven minutes. We now tried a fowl, which died in a minute and a half. We threw in another, which died before touching the ground. During these experiments we experienced a heavy shower of rain; but we were so interested by the awful scene before us, that we did not care for getting wet. On the opposite side, near a large stone, was the skeleton of a human being, who must have perished on his back, with the right arm under his head. From being exposed to the weather, the bones were bleached as white as ivory. I was anxious to procure this skeleton, but any attempt to get at it would have been madness. After remaining two hours in this Valley of Death we returned, but found some difficulty in getting out...... The human skeletons are supposed to be those of rebels who had been pursued from the main road, and taken refuge in the different valleys; as a wanderer cannot know his danger till he is in the valley, and, when once there, he has not the power or the presence of mind to return."

Mr Loudon conceives that there is a great difference between this valley and the Grotto del Cane, near Naples. In the Grotto the air is confined to a small aperture, whilst in the valley the circumference is fully half a mile, and not the least smell of sulphur, nor any appearance of an eruption having taken place near it, although the whole chain of mountains is volcanic, and there are two craters which constantly emit smoke, at no great distance from the side of the road at the foot of the Djienz. It thus appears that the story told by Foersch is an entire fabrication, and that the notion of a poison-tree is a pure romance; but, like most fictions, it has a thread of truth interwoven in its texture, some of the circumstances agreeing with those above stated, but at the same time proving that Foersch had never visited the Valley of Death.

POLAND.

History.

POLAND, a country of Europe, was, in its largest extent, bounded on the north-west by the Baltic Sea, with the ports of Dantzig, Elbing, Libau, and Windau; on the north and east by Muscovy, and the rivers Dwina and Dnieper, forming part of the frontier of the two countries; on the south by the possessions of the Turkish empire, Wallachia and Moldavia, and Hungary, separated by the Carpathian Mountains; and on the west by Silesia, and the possessions of the duchy of Brandenburg, the present kingdom of Prussia.

Before the year 1772, that is, prior to the first partition, the boundaries of Poland were not materially altered. At that period, the whole territory included under this denomination comprised more than 13,000 square geographical miles, and upwards of 15,000,000 of inhabitants. Excepting the palatinates of Podolia, some parts of Volhynia, Gallicia, Sandomir, and Cracow, this tract of land presents in the greater part one immense plain, where a mountain or a hill is scarcely to be met with. But in the southern part of Poland, the ground rises to a certain degree of elevation, until it reaches the chain of the Carpathian Mountains, which at one extremity abuts on the Rhine, and at another on the Danube. The highest summit of this range is the Great Krapak, the elevation of which has been ascertained to be 10,220 feet above the level of the sea.

The Poles, considered as a nation, are not of very ancient date. Prior to the ninth century, they were divided into a multitude of independent tribes, each governed by its respective chief; and, except in cases of invasion, where the necessity of self-defence produced combination, they acknowledged no general head or chief. Like most other people, however, they lay claim to an antiquity sufficiently venerable, and trace their origin back to one of the immediate descendants of Noah, who, according to them, colonized this part of ancient Sarmatia. But the absurdity of such a claim being too obvious to be long supported, especially amongst a people who never had even a fabulous history, less extravagant chroniclers were content with assigning to Lech or Lesko, who is said to have reigned about the middle of the sixth century, the honour of their incorporation as a nation. Nor can it be doubted that even this era is much too early. As the laws of historical evidence became better understood, it was accordingly given up as untenable, and the authentic opening of Polish history has been brought down three centuries; that is, to the accession of Ziemowitz, in the year 860. Lastly, it was reserved for the Polish writers of our own time, Lelewel, Niemcewitz, Golembrowski, Zielinski, and others, to abstract another century from the national existence, and to proclaim Miecislas I. as the true founder of the Polish monarchy.[1]

Polish sovereigns at first only styled dukes.

The sovereigns of Poland had at first the title of dukes or generals, as if their office had been only to lead the armies into the field. The first of these is now generally allowed to have been Lech or Lecht; and to this day Poland is called by the Tartars the kingdom of Lech. Busching, however, gives a different account of the origin of the Poles. Sarmatia, he observes, was an extensive country, inhabited by a variety of nations of different names; as he supposes the Poles to be the descendants of the ancient *Lazi*, a people who lived in Colchis, on the Euxine; hence the Poles are sometimes called *Polazi*. Having crossed several rivers, they entered Posnania, and settled on the borders of the Warta, whilst their neighbours the Zechi settled on the Elbe, in the 550th year of Christ.

History.

Of the transactions of Lech during the time he enjoyed the sovereignty we have no certain account. His successor was named Viscimar, and is generally supposed to have been the nephew of Lech. He was a warlike and successful prince, who subdued many provinces of Denmark, and built the city of Wismar, so called from the name of the sovereign. But the Danish historians take no notice of his wars with their country, nor do they even mention a prince of this name.

Change in the form of government.

After the defeat of Viscimar, the nobility were upon the point of electing a sovereign, when the people, suffering under the burdens occasioned by the wars of Viscimar, unanimously demanded another form of government. At first the nobility pretended to yield, though with great reluctance; but they afterwards determined on such a form of government as threw all the power into their own hands. Twelve palatines, or vayvodes, were chosen; and the Polish dominions divided into as many provinces. But these palatines exercised a despotic authority within their several jurisdictions, and aggravated the misery of the people by perpetual wars; wherefore the Poles, worn out with oppression, resolved to return to their ancient form of government. For this purpose many assemblies were held; but, by reason of the opposition of the vayvodes, they all came to nothing. At last, however, the people cast their eyes upon one Cracus, whose wealth and popularity had raised him to the highest honours amongst his countrymen. According to the Poles, he was a native of Poland, and one of the twelve vayvodes; the Bohemians, however, affirm that he was a native of their country; but both agree in maintaining that he was descended from the ancient family of the Gracchi in Rome; a paternity which insured assent by reason of its absurdity. Cracus, however, is said to have signalized himself against the Franks, whom he overthrew in some desperate engagements, and afterwards founded the city of Cracow, whither he transferred the seat of his government. He did not enlarge his dominions, but he did more than this; he made his subjects happy by many excellent laws and regulations. At last, after a long and glorious reign, he was assassinated by a nobleman who aspired to the crown.

Cracus left three children; Cracus, Lech, and a daughter named Wenda. The first succeeded to the dukedom in virtue of his birthright, but was soon afterwards murdered by his brother Lech. The latter, however, did not long profit by this fratricide. His crime having been discovered, he was deposed and banished by his subjects, and his sister Wenda was declared duchess. This princess was beautiful and accomplished; and soon after she had been raised to the sovereignty, Rudiger, a German prince, sent an ambassador demanding her in marriage, and threatening war if his proposals were refused. Wenda marched in person against him at the head of a numerous army; but the event proved fatal both to Rudiger and herself. The troops of Rudiger having abandoned him without striking a blow, he killed himself in despair; and Wenda was so much concerned for his death that she is said to have drowned herself in the Vistula.

The family of Cracus having become extinct by the death of Wenda, and the Poles being again at liberty to choose a new sovereign and a new form of government, through a natural levity restored the vayvodes, notwithstanding all that they had formerly suffered from them. The consequences were precisely the same as before. The vayvodes abused their power; the people were oppressed; and the state was distracted between foreign wars and civil contentions. The Hungarians and Moravians had invaded Poland, and were opposed only by a handful of men almost ready to surrender at discretion. Subjugation and ruin appeared inevitable; when one Prezemislas, a private soldier, contrived a stratagem by which the numerous forces of the enemy were overthrown, and for his valour was rewarded with the dukedom. We are ignorant of the other transactions of his reign; but historians inform us that he died deeply regretted, leaving no issue.

---

[1] The word *Pole* is not older than the tenth century, and seems to have been originally applied not so much to the people as to the region they inhabited; *Polska*, in the Sclavonic language, signifying a field or plain.

On the death of Prezemislas several candidates appeared for the throne; but the Poles determined to prefer him who should overcome all his competitors in a horse-race. A stone pillar was erected near the capital, on which were laid all the ensigns of the ducal authority; and a herald proclaimed, that he who first arrived at that pillar from a river at some distance, named Pradnik, should obtain the prize. A Polish lord named Lech or Lesko resolved to secure the victory by artifice; for which purpose he caused iron spikes to be driven all over the course, reserving only a path for his own horse. The fraudulent design took effect; all the rest of the competitors were dismounted, some being severely hurt by their fall; and Lesko was about to be proclaimed victor, when, unluckily for him, a peasant who had found out the artifice opposed the ceremony. An examination of the fact immediately took place; Lesko was torn in pieces, and the ducal authority conferred upon the peasant.

The name of the new monarch was also Lesko. Having thus attained the sovereignty, he conducted himself with great wisdom and moderation. Though he possessed the qualities of a great warrior, and extended his dominions on the side of Moravia and Bohemia, yet his chief delight was to render his subjects happy by cultivating the arts of peace. In the decline of life he was obliged to engage in a war with Charlemagne, and is said by some to have fallen in battle; though others assert that he died a natural death, at an advanced age, when the springs of life were quite worn out.

Lesko II. was succeeded by his son Lesko III. who inherited all his father's virtues. He suppressed an insurrection in the Polish provinces; and having led his army against the Greek and Italian legions who had overrun Pannonia, he gained a complete victory over his enemies. Nor was his valour more conspicuous in the battle than his clemency in the victory. He dismissed all his prisoners without ransom, demanding no other conditions than that they should never again disturb the peace of Poland, or the allies of that kingdom. This duke is said to have been endowed with many virtues, and is charged only with the vice of incontinence. He left twenty natural children, and only one legitimate son, named Popiel, to whom he bequeathed the sovereignty. The latter removed the seat of government from Cracow to Gnesna, and was succeeded by his nephew Popiel II. then a minor.

This young king behaved with great propriety as long as he was under the tuition of others; but as soon as he had got the reins of government into his own hands the face of affairs was altered. Lesko III. had promoted his illegitimate children to the government of different provinces; and they had discharged the duties of their offices in such a manner as showed that they were worthy of the confidence reposed in them. But as soon as he came of age, Popiel, seduced by his wife, an artful and ambitious woman, removed them from their posts, treated them with the utmost contempt, and at last found means to poison them all at an entertainment. A dreadful punishment, however, is said to have awaited his treachery and cruelty; and he perished miserably, with all his house.

The nation now became a prey to civil discord, at the same time that it was harassed by a foreign enemy; and the state seemed to be on the verge of dissolution, when Piast was proclaimed duke in 842. The reign of Piast was the golden age of Poland. He engaged in no foreign wars; he was harassed with no domestic commotions; respect and honour met him without, abundance and contentment within. This excellent monarch, from whom those of ducal or regal dignity were called Piast, died in the year 861, and was succeeded by his son Ziemowitz, who was of a more warlike disposition than his father, and first introduced regular discipline amongst the Polish troops. He maintained a respectable army, and took great pains to acquire a perfect knowledge of the art of war. Hence he was victorious in all his battles, retook from the Germans and Hungarians all that they had gained by conquest, and, at the same time, greatly enlarged his own dominions.

Christianity introduced by Miecislas.

After his death nothing remarkable happened in Poland till the time of Miecislas I., who attained the ducal authority in 964. He was born blind, and continued so for seven years, after which he recovered his sight without using any medicine; a circumstance so extraordinary, that in those times of ignorance it was accounted a miracle. In his reign the Christian religion was introduced into Poland. The most probable account of the manner in which Christianity was introduced is, that Miecislas having by ambassadors paid his addresses to Dombrowka, daughter of the king of Bohemia, the lady rejected his offer unless he should suffer himself to be baptized. To this the duke consented, and, after having been instructed in the principles of Christianity, he was baptized. He founded the archbishoprics of Gnesna and Cracow; and appointed St Adelbert, who had been sent by the pontiff to propagate Christianity in Poland, primate of the whole kingdom. On the birth of his son Boleslas he redoubled his zeal, founding several bishoprics and monasteries, and ordering that, when any part of the Gospel was read, the hearers should half draw their swords, in testimony of their readiness to defend the faith. But he was too devout to attend to the duties of a sovereign, and suffered his dominions to be ravaged by the sovereign of Russia. Yet, with all his devotion, he could not obtain the title of king from the pope, though he had warmly solicited it. That title was afterwards conferred on his son, who succeeded to all his dominions.

Boleslas I. king of Poland.

Boleslas I. surnamed Chobry, or the Valiant, succeeded to the sovereignty in 999. He also professed and cherished Christianity, and was a man of great valour and prudence. The first transaction of his reign, however, savoured much of the fanciful piety of those times. He removed from Prague to Gnesna the relics of a saint, which he had purchased at a considerable price. The Emperor Otho III. made a pilgrimage to the tomb of this saint, where he was hospitably received by Boleslas, whom, in return, Otho invested with the regal dignity; an act which was confirmed by the pope. But this new dignity added nothing to the power of Boleslas. He now indeed affected more state than before; his body-guards were considerably augmented; and, whenever he stirred out of his palace, he was constantly attended by a numerous and splendid retinue. In this way he inspired his people with an idea of his greatness, and also of their own importance, which was perhaps necessary for the accomplishment of a design he had formed, namely, an offensive war with Russia; but when he was on the point of setting out on this expedition, he was prevented by the breaking out of a war with the Bohemians.

Conquest of Bohemia.

The elevation of Boleslas to the regal dignity had excited the envy of the Duke of Bohemia, who having solicited the same honour for himself, had been refused; and his jealousy was further excited by the connection between Boleslas and the emperor, the former having married Rixa, the emperor's niece. Without any provocation, therefore, or giving the least intimation of his design, the Duke of Bohemia entered Poland at the head of a numerous army, committing everywhere the most dreadful devastations. Boleslas immediately marched against him, and the Bohemians retired with precipitation. Scarcity of provisions, however, and the inclemency of the season, prevented Boleslas at that time from pursuing; but as soon as these obstacles were removed, he entered Bohemia at the head of a formidable army, with a fixed resolution to inflict ample vengeance. The Bohemians were altogether unable to resist; neither had they the courage to venture a battle. So great, indeed, was the cowardice of the duke or his army, that they suffered Prague, the capital of the duchy, to be taken after a siege of two years, having never, during that time, ventured to raise the siege by attacking the Polish army. The taking of this city was quickly followed by the reduction of places of inferior note; but though Boleslas was in possession of almost all the fortresses in Bohemia, he could not believe his conquests complete until he became master of the duke's person. This unfortunate prince had shut himself up with his son in his only remaining fortress of Wissogrod, where he imagined he would be able to foil all the attempts of the Polish monarch. In this, however, he was deceived. Boleslas invested the place, and made his approaches with such rapidity, that the garrison, dreading a general assault, resolved to capitulate, and persisted in their resolution notwithstanding all the entreaties and promises of the duke. This unhappy prince therefore fell into the hands of his enemies, and had his eyes put out by Boleslas; after which his son Jaromir was sent into confinement.

Other advantages gained by him.

From Bohemia Boleslas marched towards Moravia, and no sooner had he arrived on the frontier than the whole province submitted without a blow. He then resumed his intention of invading Russia, for which he had now a fair opportunity, by reason of a civil war which raged with violence amongst the children of the Grand Duke Vladimir. The chief competitors were Jarislas and Swiantopelk. The latter, having been defeated by his brother, was obliged to take refuge in Poland, where he used all the arguments in his power in order to induce Boleslas to avenge his cause. Boleslas having already an intention of invading that country, needed but little entreaty; and therefore marched towards Russia at the head of a numerous army, giving out that he had no other design than to revenge the injustice done to Swiantopelk. He was met on the banks of the river Bug by Jarislas at the head of an army much superior in number to his own; and for some days the Polish army was kept in check by the Russians. At last Boleslas, growing impatient, resolved to pass the river at all events; and therefore forming his cavalry in the best manner for breaking the torrent, he exposed his own person to its utmost force. Encouraged by his example, the Poles advanced breast-deep in the water to the opposite shore, whence the enemy made every resistance in their power. In spite of all opposition, however, the Poles reached the bank, and soon gained a complete victory, Jarislas being obliged to fly to Kiow. This city was immediately invested; but Jarislas retired farther into the country to recruit his army, leaving the city to its fate. The garrison made a brave defence, but were at last compelled to surrender at discretion.

Swiantopelk raised to the throne of Russia.

Though the king of Poland had now become master of the greater part of Russia, he knew that the only means of keeping the country in subjection was by placing a natural sovereign over the inhabitants. For this reason he reinstated Swiantopelk, though his pretensions were still disputed by Jarislas. The latter had formed a flying camp, and meditated a scheme of surprising and carrying off his brother; but having failed in this attempt, he retired to Novogorod, where the attachment of the inhabitants enabled him to make some resistance, till at last he was again defeated by Boleslas, which seemed to give the finishing blow to his affairs. In the perfidious and ungrateful Swiantopelk, however, the king of Poland now experienced a more dangerous enemy than he had found in Jarislas.

Death of Boleslas.

The Russian prince, imagining himself a dependent on Boleslas, formed a conspiracy, which had for its object nothing less than the destruction of Boleslas and his whole army. The massacre was already begun when Boleslas received intelligence of this daring and profligate scheme. The urgency of the case admitted of no delay. The king therefore mounted his horse, and having with the utmost haste assembled part of his army, fell upon the traitors with such fury that they were obliged to betake themselves to flight, and Boleslas got safe back into Poland. But in the mean time Jarislas, assembling fresh forces, pursued the Polish army; and having come up with them just as one half crossed the Borysthenes, attacked them with the utmost fury. Boleslas defended himself with the greatest resolution; but, by reason of his forces being divided, victory remained for a long time doubtful. At last, when the army had wholly crossed, the Russians were entirely put to the rout, and a terrible carnage ensued. The victory, however, though complete, was not decisive; wherefore Boleslas thought proper to continue his retreat, without attempting to conquer a country too extensive ever to be kept in subjection.

Boleslas, still unsated with victory, now meditated the conquest of Prussia, and also Pomerania, which had, in the former wars, been dismembered from Poland. His arms were attended with equal success in both attempts; indeed the terror of his name seemed to serve all the purposes of a formidable army. These, however, seem to have been designed as his last warlike enterprises; for he now applied himself to enact wholesome laws for the benefit of his people. But whilst he was thus occupied, Jarislas assembled a numerous army, with which he appeared on the frontiers of Poland. Boleslas, though now advanced in years, marched against his adversaries, and met them on the banks of the Borysthenes, where, attacking the enemy before they had time to draw up in order of battle, he totally defeated them. The Russians being seized with a panic, Jarislas was hurried away, and almost trampled to death by the fugitives. Many thousand prisoners were taken, but Boleslas released them on very easy conditions; contenting himself with an inconsiderable tribute, and endeavouring to engage the affections of the people by his kindness. This well-timed clemency produced such a happy effect, that the Russians voluntarily submitted to his jurisdiction, and became once more his subjects. Soon after this he died, in the year 1025, after having greatly extended his dominions, and, as some say, rendered his subjects happy.

Miecislas II.

Boleslas was succeeded by his son Miecislas II.; but the latter possessed none of the great qualities of his father, being indolent, corrupt, and debauched in his behaviour. In the beginning of his reign, the Russians, Bohemians, and Moravians revolted; but as the spirit and discipline introduced by Boleslas still remained in the Polish army, Miecislas found no great difficulty in reducing them again to obedience; after which, having devoted himself entirely to voluptuousness, he was seized with a frenzy, which put an end to his life in the year 1034.

Rixa, and her son Casimir, expelled.

The bad qualities of this prince proved very detrimental to the interest of his son Casimir, though the latter had received an excellent education, and possessed many virtues. Instead of electing him king, therefore, the Poles chose Rixa, his mother, queen-regent. But she proved tyrannical, and so partial to her countrymen the Germans, that a rebellion ensued; and she was forced to fly to Germany, where she obtained the protection of the emperor, by means of the immense treasures of Boleslas, which she had caused to be transported thither. Her insolent behaviour and consequent expulsion proved still more fatal to the affairs of

Casimir than even that of his father. He was immediately driven out of the kingdom; and aa a civil war took place, there appeared a great many pretenders to the crown. To the miseries thus occasioned were added those of a foreign war. The Bohemians and Russians invaded the kingdom in different places, committing the most dreadful ravages; and the consequence of these accumulated distresses was, that the nobility came at last to the resolution of recalling Casimir, and electing him sovereign.

Ca mir re led an made ki

The only difficulty was where to find the fugitive prince; for he had been gone five years, and nobody knew the place of his retreat. At length, by sending an embassy to his mother, it was found out that he had at first retired into France, where he applied closely to study at the university of Paris; that afterwards he went to Italy, where, for the sake of subsistence, he took upon him the monastic habit; and that having returned to France, he had obtained some preferment in the abbey of Clugny. Nothing now obstructed the prince's return but the sacred function with which he was invested. A dispensation was, however, obtained, by which he was released from his ecclesiastical engagements, on condition that he and all the kingdom should become subject to the capitation tax, called Peter's pence. Some other conditions of less consequence were added, such as, that the Poles should shave their heads and beards, and wear a white linen robe at festivals, like other professors of the Catholic religion. Great preparations were also made for the reception of the young prince; and he was met on the frontier by the nobility, clergy, and forces of the nation, by whom he was conducted to Gnesna, and crowned by the primate with more than usual solemnity. He proved a virtuous and pacific prince, equal to the difficulties of his situation, worthy of the confidence of the people, and anxious to repair the evils which had so long afflicted his country. Casimir, however, evinced his courage in subduing the banditti by which the country was infested, in re-establishing order, and in restoring the dominion of the laws. By marrying the Princess Mary, sister of the Duke of Russia, all quarrels with his most formidable enemies were for the time extinguished. In a word, the kingdom flourished during his reign, and, from the wisdom and stability of the administration, became more respectable than it could have been rendered by many victories. After a happy reign of sixteen years, he died beloved and regretted by all his subjects.

Bo las II.

By the happy administration of Casimir the kingdom recovered sufficient strength to carry on successful wars against its foreign enemies. Boleslas II., the son of Casimir, an enterprising and valiant prince, succeeded to the throne, and soon rendered himself so famous that three unfortunate princes took refuge at his court, having been expelled from their dominions by their rebellious subjects. These were, Jaromir, brother of Wratislas duke of Bohemia; Bela, brother of the king of Hungary; and Zaslaf duke of Kiow, eldest son of Jarislas duke of Russia, and cousin to the king of Poland. Boleslas determined to redress all their grievances; but whilst he deliberated upon the most proper means of so doing, the Duke of Bohemia, dreading the consequences of Jaromir's escape, assembled an army, and, without any declaration of war, marched through the Hercynian forest, desolated Silesia, and laid waste with fire and sword the frontiers of Poland. Boleslas marched against him with a force greatly inferior; but, by dint of superior capacity, cooped up his adversary in a wood, where he reduced him to the greatest distress. In this extremity the duke sent proposals for accommodation; but these were rejected with disdain by Boleslas; upon which the former, ordering fires to be kindled in his camp, as if he designed to continue there, removed with the utmost silence in the night-time, and marching through narrow defiles, advanced several leagues before Boleslas received intelligence of his retreat. The king pursued the fugitive, but in vain; and, after ravaging the frontiers of Moravia, he returned to his own dominions. The next year Boleslas entered Bohemia with a numerous army; but the duke, unwilling to encounter such a formidable adversary, submitted to such terms as Boleslas thought proper to dictate. In these the king of Poland stipulated for certain conditions in favour of Jaromir, which he took care to see punctually executed; and he next determined to march towards Hungary, to assist the fugitive prince Bela.

This prince had for some time been solicited by a party of disaffected nobility to return, his brother, the reigning king, having, by his tyrannical behaviour, alienated the hearts of his subjects. As soon, therefore, as Boleslas had finished the war in Bohemia, he was solicited by Bela to embrace the present favourable opportunity for putting him in possession of the kingdom of Hungary. This the king readily complied with; and both princes entered Hungary, by different routes, each at the head of a numerous body. The king of that country, however, was not disconcerted by such a formidable invasion; and, being largely assisted by the emperor, advanced against his antagonists with a great army, in which there were a numerous body of Bohemians, who had come to his assistance in direct violation of the treaty subsisting between the duke and the king of Poland. A decisive battle was at length fought, in which the Germans behaved with the greatest valour, but were entirely defeated through the treachery of the Hungarians, who in the heat of the battle deserted and went over to Bela. Almost all the foreign auxiliaries were killed on the spot; the king himself was seized, and treated with such cruelty that he died of a broken heart; and Bela was placed on the throne without further opposition, except from a revolt of the peasants, which was soon quelled by the Polish army.

Boleslas projects the conquest of Russia.

Boleslas, having thus succeeded in two great enterprises, began to look upon himself as invincible; and, instead of designing only to assist Zaslaf, as he had at first intended, now projected the subjugation of the whole country. He had indeed a claim to the sovereignty in virtue of his descent from Mary, queen of Poland, the sister of Jarislaf; and this he endeavoured to strengthen by marrying a Russian princess. Having, therefore, assembled a numerous and well-disciplined army, he entered the duchy of Kiow, and was there opposed by Uscheslaf, who had usurped the sovereignty, with a great body of forces. Boleslas, however, continuing to advance, the Russian prince, intimidated by the number and order of his enemies, deserted his own troops, and fled privately with a slender retinue, upon which his force dispersed. The inhabitants of the city of Kiow now called to their assistance two brothers of Uscheslaf; but these princes acting the part of mediators, procured pardon for the inhabitants from Zaslaf, their natural sovereign; and with the same facility the two princes recovered all the other dominions belonging to Zaslaf. In the mean time the king of Hungary died; a revolt immediately ensued; and the two sons of Bela were on the point of being deprived of their paternal dominions. This Boleslas no sooner heard of than he marched directly into Hungary, where, by the terror of his name alone, he re-established tranquillity, and confirmed the princes in the enjoyment of their kingdom. In the mean while Zaslaf was again driven from his territories; all the conquests that had formerly been made were lost; and his brothers became more powerful than ever. The king's vigour, however, soon disconcerted all their measures. He ravaged the territories composing two palatinates, reduced the strong city of Wolyn, and transported the booty to Poland. The campaign was finished by a battle, which proved so bloody, that though Boleslas proved victorious, his army was so weakened that he could not pursue his conquests. In the winter he made numerous levies, and returning in the spring to Kiow, reduced it by famine. But on this occasion, instead of treating the inhabitants with cruelty, he commended their valour, and strictly prohibited his troops from pillaging or insulting them; distributing provisions amongst them with the utmost liberality.

This clemency procured the highest honour to the king of Poland. But his stay here was productive of a great disaster. Kiow being the most dissolute as well as the richest city in the north, the king and his soldiers gave themselves up to the pleasures of the place. Boleslas himself affected all the state of an eastern monarch, and contracted an inclination for the grossest debaucheries. This Russian Capua proved almost fatal to Poland. The Hungarian and Russian wars having continued for seven years, during that time the king had never been at home, excepting for the short space of three months. In the mean time the Polish women, exasperated at hearing that their husbands had neglected them, and connected themselves with the women of Kiow, raised their slaves to the beds of their masters; in other words, conspired in one general scheme of prostitution, in order to be revenged for the infidelity of their husbands.[1] Advice of this strange revolution was soon received at Kiow, where it excited violent commotions. The soldiers blamed the king for their dishonour, forgetting how much they had to accuse their own conduct in giving their wives such provocation. The effect of these discontents was a general desertion, and Boleslas saw himself suddenly left almost alone in the heart of Russia; the soldiers having unanimously resolved to return home, in order to take vengeance upon their wives and their paramours.

Civil war.

A dreadful kind of civil war now ensued. The women, knowing that they had no mercy to expect from their husbands, persuaded their paramours to take arms in their defence. They themselves fought by the side of their gallants with the utmost fury, and sought out their husbands in the heat of battle, in order to secure themselves from all danger of punishment by their death. They were, however, on the point of being subdued, when Boleslas arrived with the few remaining Poles, assisted by an army of Russians, with whom he resolved to take equal vengeance on the women, their gallants, and his own soldiers who had deserted him. This produced a carnage more dreadful than ever. The soldiers united with their former wives and their gallants against the common enemy, and fought against Boleslas and the Russians with the fury of lions. At last, however, the fortune of the king prevailed; the rebels were totally subdued; and the few who escaped the sword were tortured to death, or perished in prison.

Religious contentions.

To add to the calamities of this unhappy kingdom, the schisms which for some time had prevailed in the Church of Rome found their way also into Poland; and the animosity of parties became aggravated in proportion to the frivolous nature of their differences. But, as generally happens, the matter at length came to be a contention for wealth and power between the king and clergy. Bloodshed followed. The Bishop of Cracow was, like another Thomas a-Becket, massacred in the cathedral whilst he was performing the duties of his office. Violence filled the land, and anarchy reigned supreme. This and other crimes in a short time brought on signal vengeance. Pope Gregory VII. thundered out anathemas against the king, released his subjects from their allegiance, deprived him of the titles of sovereignty, and laid the kingdom under a general interdict. To this sentence Boleslas in vain opposed his authority, and recalled the spirit which had formerly rendered him so formidable. The minds of the people were so impressed with the power of the church, that they deemed it a less heinous crime to rise in rebellion against their sovereign than to oppose the authority of the holy see. Conspiracies were daily formed against the person and government of Boleslas; and the whole kingdom became a scene of confusion, so that the king could no longer continue with safety in his own dominions. He therefore fled with his son Miecislas, and took refuge in Hungary. But here also the holy vengeance of the clergy pursued him, nor did they cease persecuting him till he was brought to a miserable end. Authors differ respecting the manner of his death. Some say that he was murdered by the clergy as he was hunting; others, that he killed himself in a fit of despair; whilst one author informs us that he wandered about in the woods of Hungary, lived like a savage upon wild beasts, and was at last devoured by dogs. The greatest number, however, allege, that being driven from place to place by the persecutions of the clergy, he was at last obliged to become a cook in a monastery at Carinthia, where in this mean occupation the king of Poland ended his days, probably in peace.

The interdict removed.

The destruction of Boleslas was not sufficient to allay the papal resentment. It extended to the whole kingdom of Poland. Miecislas, the son of Boleslas, was not suffered to ascend the throne; the kingdom continued under a severe interdict, which could be removed only by the most abject concessions; and, besides the tax called Peter's pence, new impositions were added of the most oppressive nature; until at length the pontiff, having impoverished the country, consented that the brother of the deceased monarch should be raised to the sovereignty, but only with the title of duke.

Uladislas.

This prince, named Uladislas, being of a meek disposition, with little ambition, thought it his duty to acquiesce implicitly in the will of the pope. Having therefore accepted the terms offered, he sent an embassy to Rome, earnestly entreating the removal of the interdict. The request was granted; but all his endeavours to recover the regal dignity proved fruitless, the pope having, in conjunction with the emperor of Germany, conferred that honour on the Duke of Bohemia. This was extremely mortifying to Uladislas, but it was absorbed in considerations of the utmost consequence to himself and his dominions. Russia availed itself of the recent disturbances to throw off the yoke; and this revolt drew after it that of Prussia, Pomerania, and several other provinces. The smaller provinces, however, were soon reduced; but the duke had no sooner returned to Poland than they again rebelled, concealing their families in impenetrable forests. Uladislas marched against them with a considerable army; but was entirely defeated, and obliged to return in disgrace. Next year, however, he had better fortune. Having led against them a more numerous army than before, he compelled them to submit, and deliver up the ringleaders of the revolt to be punished as the duke thought proper.

But no sooner were the Pomeranians reduced, than civil dissensions took place. Sbigniew, the son of Uladislas by a concubine, was placed by the discontented nobility at the head of an army to subvert his father's government, and dispute the title of Boleslas, the legitimate son of Uladislas, to the succession. The war was terminated by the defeat and captivity of Sbigniew, who was at first confined, but afterwards released on condition that he should join his father in punishing the palatine of Cracow. Before this could be effected, however, the palatine found means to effect a reconciliation with the duke; and the young princes being displeased with this, a war ensued between them and their father. At length, however, the palatine of Cracow was banished, and the princes submitted; after which, Uladislas, having chastised the Prussians and Pomeranians, who had again revolted, died in the year 1103, in the fifty-ninth year of his age.

---

[1] This prostitution or bigamy must have been all but universal, since only one lady is mentioned who had the virtue to resist the strange epidemic passion with which the Polish matrons appear to have been seized. Her name, which history has been careful to preserve, was Margaret, the wife of Count Nicolas de Zembosin

B slas II

Uladislas was succeeded by his son Boleslas III. who divided his dominions equally between his brother Sbigniew and himself. But the former being dissatisfied with his share, raised cabals against his brother; and a civil war was for some time prevented by the good offices of the primate. At last, Sbigniew, having privately stirred up the Bohemians, Saxons, and Moravians, against his brother, made such formidable preparations as threatened the conquest of all Poland. Boleslas, unprovided with forces to oppose such a formidable power, had recourse to the Russians and Hungarians, who readily embraced his cause, in expectation of turning it to their own advantage. Ultimately, however, Sbigniew was defeated, and might have easily been obliged to surrender at discretion, had not Boleslas generously left him in quiet possession of the duchy of Mazovia. This kindness the ungrateful Sbigniew repaid by entering into another conspiracy; but the plot being discovered, he was seized, banished, and declared a traitor if ever he again set foot in Poland. Even this severity, however, did not produce the desired effect. Sbigniew having persuaded the Pomeranians to arm in his behalf, was defeated, taken prisoner, and again banished. All the nobility now solicited the king to put the ungrateful traitor to death; but that generous prince could not think of polluting his hands with the death of his brother. He even took him back to Poland, and appointed him a maintenance suitable to his rank; but he soon had reason to repent of his kindness. His unnatural brother soon began to raise fresh disturbances, and at length met with the death which he had so well deserved.

W with th mpe- ro enry V.

Boleslas was scarcely freed from the intrigues of his brother, when he found himself in greater danger than ever, from the ambition of the Emperor Henry V. The emperor had attacked the king of Hungary, with whom Boleslas was in close alliance, and from whom he had received assistance in his greatest distress. The king of Poland determined to assist his friend, and therefore made a powerful diversion in Bohemia, where he repeatedly defeated the imperialists. The emperor then collecting all his forces, ravaged Silesia, and even entered Poland, where he laid siege to the strong town of Lubusz; but he was at last obliged to abandon the enterprise, after having sustained severe loss. Henry, in no degree discouraged, penetrated still farther into Poland, and was laying waste all before him, when the superior skill of Boleslas compelled him to retire. Enraged at this disappointment, Henry laid siege to Glogau, in hopes of drawing the Poles to an engagement before he should be obliged to evacuate the country. The fortifications of the place were weak, but the spirit of the inhabitants supplied their deficiencies. At last, however, they were on the point of surrendering, and had actually agreed to give up the place, provided they did not receive any succours within a definite time. But Boleslas, determined not to allow so brave a garrison to fall a sacrifice to their loyalty, prevailed on the besieged to break the capitulation rather than surrender when they were on the point of being delivered. All this was transacted with so much secrecy, that the emperor advanced, without thoughts of meeting any resistance, to take possession of the city; but being received by a furious discharge of arrows and javelins, he was so incensed that he resolved to storm the place, and not give any quarter. On the approach of the army, the imperialists were astonished to see not only the breaches filled up, but new walls, secured by a wet ditch, reared behind the old, and erected during the suspension of hostilities by the industry of the besieged. The attack, however, went on; but the inhabitants, animated by despair, defended themselves with incredible valour, and at last obliged the imperialists to raise the siege. Next day Boleslas arrived, and pursued the emperor with such vigour that he obliged him to retreat with disgrace into his own country. This soon brought on a peace, which was confirmed by a marriage between Boleslas and the emperor's sister.

Boleslas brought into difficulties.

Hitherto the glory of Boleslas had equalled, or perhaps even eclipsed, that of his namesake and predecessor Boleslas the Great; but about the year 1135 he was brought into difficulties, and even disgrace, by his own credulity. Imposed on by an artful story trumped up by a certain Hungarian, who had insinuated himself into his affections, he conferred on that adventurer the government of Wislica, a strong town on the river Nida. But the traitor gave up the place to the Russians, who pillaged and burned it, at the same time carrying the inhabitants into slavery. Boleslas, incensed, immediately entered into a war with Russia, by which he only heaped one calamity upon another. Having received a deputation from the inhabitants of Halitz to implore his assistance, Boleslas marched to their relief with a choice body of troops; but as he was preparing to enter the town he was attacked by the whole Russian army, and, after a most violent conflict, entirely defeated. The unfortunate prince was so much afflicted by this reverse, that in a short time he died, after having reigned thirty-six years.

Poland divided amongst the children of Boleslas.

Boleslas, by his will, divided his dominions equally amongst his four sons. Uladislas, the eldest, had the provinces of Cracow, Sieradz, Lencsysa, Silesia, and Pomerania. Boleslas, the second son, had for his share the palatinates of Culm and Kujavia, with the duchy of Mazovia. The palatinates of Kalszh and Posen fell to Miecislas, the third son; and to Henry, who was the fourth, were assigned those of Lublin and Sandomir. Casimir, the youngest child, then an infant in the cradle, was entirely forgotten, and no provision made for him. There have been but very few instances where dominions were thus divided, that the princes remained satisfied with their respective shares; neither did the sons of Boleslas long continue at peace with one another. By the will of the duke, all the brothers were obliged to own the supremacy of Uladislas, who was declared duke of Poland; they were restrained from forming alliances, declaring war, or concluding peace, without his approbation; they were obliged to take the field with a certain number of troops whenever the duke required it; and they were forbidden to meddle with the guardianship of the infant Prince Casimir, his education being left entirely to the sovereign.

A civil war.

The harmony of the princes was first disturbed by the ambition of Christina, the wife of Uladislas, who formed a scheme to get possession of all Poland, and deprive the younger children of the benefit of their father's will. Having obtained her husband's concurrence, she assembled the states of Poland, and made a long speech, showing the dangers which might arise from a partition of the ducal dominions amongst so many; and concluded with attempting to show the necessity of revoking the ratification of the late duke's will, in order to insure the obedience of the princes and the tranquillity of the republic. Many of the nobility expressed their resentment against this speech, and fully refuted every article in it. But all were afterwards gained over or intimidated by Uladislas, and none appeared to take the part of the young princes except a noble Dane, who lost his life for this generous interference.

Conduct and fate of Uladislas.

Uladislas having now got the nobility on his side, first drove Boleslas from his territories, and next marching against Henry, dispossessed him also, forcing both to take refuge with Miecislas in Posnania, where all the three brothers were besieged. Several of the nobility interposed, and employed all their influence to effect a reconciliation, but in vain. Uladislas, as inexorable as if he had received an injury, insisted that the besieged princes should surrender at discretion, and submit to the will of the conqueror. Thus driven to despair, the brothers sallied out, attacked the

History.

duke's army, and having obtained a complete victory, took all his baggage and valuable effects. Next, to improve their victory, they laid siege to Cracow. The Russians, who had at first assisted Uladislas, now abandoned him, and evacuated Poland. This obliged him to shut himself up in Cracow, whence, finding the inhabitants little disposed to stand a siege, he retired into Germany to solicit assistance. But in the mean time the city of Cracow surrendered, Uladislas was formally deposed, and his brother Boleslas raised to the supreme authority.

Boleslas. Poland invaded by the Emperor Barbarossa.

The new duke began his administration with an act of generosity towards his brother Uladislas, on whom he conferred the duchy of Silesia, which was thus separated from, and has never since been re-annexed to Poland. But this had no other effect upon Uladislas than putting him in a condition to raise fresh disturbances; and he now found means to persuade the Emperor Conrad to invade Poland. Boleslas, however, so harassed and fatigued his army by marches, ambuscades, and skirmishes, that he was soon obliged to return to his own country; and for some years Poland enjoyed profound tranquillity. During this interval Henry entered on a crusade; and though he lost almost his whole army in that enthusiastic undertaking, yet he is celebrated, by the superstitious writers of the age, as the bulwark of the church, and one of the greatest Christian heroes. Soon after the return of Henry, Poland was invaded by the Emperor Frederic Barbarossa, who had been persuaded to make the attempt by Uladislas and his wife Christina. The number of the imperialists was so great, that Boleslas and his brothers did not think proper to oppose them in the open field; they contented themselves with cutting off the convoys, placing ambuscades, harassing them on their march, and keeping them in perpetual alarm by false attacks and skirmishes. With this view the three brothers divided their forces, laid waste the country before the enemy, and burned all the towns and cities which were in no condition to stand a siege. Thus the emperor, advancing into the heart of a desolated country, where he could not subsist, was at last reduced to such a situation that he found himself obliged to solicit a conference with Boleslas. The latter was too prudent to irritate him by an unseasonable haughtiness, and therefore went to the German camp, attended only by his brothers and a slight guard. This instance of confidence proved so agreeable to the emperor, that a treaty was soon entered into, and confirmed by a marriage between Adelaide, niece of the emperor, and Miecislas, duke of Posen.

Boleslas having thus happily escaped from imminent danger, resolved to attempt the conquest of Prussia, the inhabitants of which were still heathens. Having unexpectedly invaded the country with a very numerous army, he succeeded in his enterprise. Great numbers of infidels were converted, and many churches erected; but no sooner had Boleslas withdrawn, than the inhabitants returned to their old religion. Upon this Boleslas again advanced against them with a formidable power; but being betrayed by some Prussians whom he had taken into his service and raised to posts of honour, his army was led into defiles and almost entirely cut off. Duke Henry was killed, whilst Boleslas and Miecislas escaped with great difficulty.

This misfortune was quickly followed by another. The children of Uladislas now laid claim to all the Polish dominions which had been possessed by their father, and the greater part of which had been bestowed upon Casimir; and they were supported in their pretensions by a great number of discontented Poles, together with a considerable body of German auxiliaries. Boleslas, finding himself unable to withstand his enemies by force, had recourse to negotiation, by which he gained time to recruit his army and repair his losses. An assembly of the states was then held, before which the duke fully refuted the claims of the children of Uladislas; and, to take away all pretence for renewing the civil discords of Poland, they were a second time invested with the duchy of Silesia, which for the time put an end to all disputes. After this, Boleslas applied himself to promote the happiness of his subjects, and continued thus occupied until the period of his death, which happened in the year 1174.

Miecislas.

On the death of Boleslas, the states raised his brother Miecislas to the ducal throne. But the moment that Miecislas ceased to be a subject he became a tyrant, and the slave of almost every vice; so that in a short time he was deposed, and his brother Casimir elected in his stead.

Casimir. Conquest of Russia.

Casimir was a prince remarkable for his justice and benevolence. He set himself about securing peace and establishing tranquillity in all parts of his dominions. He redressed grievances, suppressed exorbitant imposts, and assembled a general Diet, in which it was proposed to rescue the peasants from the tyranny of the nobility. This last was an affair of such consequence, that the duke hesitated to engage in it of his own authority, even though supported by the clergy. Yet it proved less difficult than had been imagined to persuade the nobility to relinquish certain privileges of a kind extremely detrimental. Influenced by the example of their sovereign, they immediately granted all that he required; and, to secure this concession in favour of the peasants, the archbishop of Gnesna thundered out anathemas against all who should endeavour to reclaim the privileges they had just renounced; whilst, to give still greater weight to this decision, the acts of the Diet were transmitted to Rome, and formally confirmed by the pope. But though the nobility in general consented to the partial retrenchment or limitation of their power, it occasioned discontent amongst some, who for this reason immediately became the partisans of the deposed Miecislas. That unfortunate prince was now reduced to such indigence, that his brother Casimir, affected by the accounts he had received, proposed, in an assembly of the Diet, to resign the sovereignty in favour of Miecislas. To this proposition, however, the states replied in the most peremptory manner; desiring him never again to mention the subject to them, lest they should be under the necessity of deposing him; and intimating their determination that his brother should never more have the dominion of Poland. Casimir, however, was so much concerned on account of his brother's misfortunes, that he tried every method to relieve him, and even connived at the arts that were practised by some discontented noblemen to restore him. But this generous and amiable conduct was repaid by the grossest ingratitude. Miecislas used every art to wrest from his brother the whole of his dominions, and actually conquered the provinces of Mazovia and Cujavia; but of these he was soon dispossessed, and only some places in Lower Poland were left him. Nor was this all. On occasion of a report that Casimir had been poisoned in an expedition into Russia, he surprised the city of Cracow. But the citadel refused to surrender, and his hopes were entirely blasted by the return of Casimir himself. The last action of this amiable prince was the conquest of Russia, which he effected rather by the reputation of his wisdom and generosity than by the force of his arms. The people of that country voluntarily submitted to a prince so famed for his benevolence, justice, and humanity. Soon after his return he died at Cracow, lamented as the best prince that had ever filled the throne of Poland.

Civil war between Lesko and Miecislas.

Casimir left one son, named Lesko, an infant; but the states, dreading the consequences of a long minority, hesitated to appoint him sovereign. At last, however, Lesko was nominated, chiefly through the interest he had obtained by reason of his father's virtues. The consequence was precisely what might have been expected. Miecislas formed an alliance against him with the Dukes of Oppeln, Pomerania, and Breslau; and having raised all the men in Lower Poland fit to bear arms, took the road to Cracow with a numerous army. On the banks of the river Mozgarva a sanguinary conflict ensued; but both sides were so much weakened that they were forced to retire for some time, in order to repair their losses. Miecislas was first ready for action, and therefore had the advantage. But he thought proper to employ artifice rather than force; and having attempted in vain to corrupt the guardians of Lesko, he entered into a compact with the Princess Helen, his mother. Representing in the strongest manner the miseries which would ensue from her refusal of the conditions he proposed, he stipulated to adopt her sons Lesko and Conrad as his own; to surrender the province of Cujavia for their present support; and to declare them heirs to all his dominions. The principal nobility opposed this accommodation; but it was accepted by the duchess in spite of all their remonstrances; and Miecislas was once more put in possession of the capital, after having taken a solemn oath to execute punctually every article of the treaty.

Mi slas re red.

It is not to be supposed that a prince of such a perfidious disposition as Miecislas would pay much regard to the obligations of a simple contract. It was a maxim with him, that a sovereign is no longer obliged to observe his oath than whilst it is neither safe nor beneficial to break it. Having therefore got all the power into his hands, he behaved in the same manner as if no treaty with the Duchess Helen had ever subsisted. The princess, perceiving herself duped, formed a strong party, and having excited a general insurrection, the rebellion proved successful. Miecislas was expelled from Cracow, and on the point of being reduced to his former indigence, when he found means to foment a quarrel between the duchess and the palatine of Cracow, and thus once more turned the scale in his favour. The forces of Miecislas now became superior, and he regained possession of Cracow; but did not long enjoy his prosperity. He fell a victim to intemperance, and Lesko was restored to the sovereignty in the year 1206.

Po d ra- vag by the ar- tars

The government of Lesko was the most unfortunate of any of the sovereigns of Poland. In his time the Tartars made an irruption into that country, and everywhere committed the most cruel ravages. At last they came to an engagement with the Poles, assisted by the Russians, and, after an obstinate conflict, obtained a complete victory. This incursion, however, terminated as precipitately as it had commenced. Without any apparent reason, they retired, just as the whole kingdom was preparing to submit; but the devastations they had committed produced a famine, which was soon followed by a plague that depopulated one of the most populous countries of the north. In this unhappy situation of affairs, death ended the misfortunes of Lesko, who was assassinated by his own subjects. A civil war followed his death; and the history of Poland is for some time so confused that it is difficult to say who was his successor. During this unfortunate state of the country, the Tartars made a second irruption, laid all waste before them, and were advancing towards the capital, when they were attacked and defeated with great slaughter by the palatine of Cracow, with only a handful of men. The power of the enemy, however, was not broken by this victory. Next year the Tartars returned, and committed barbarities such as can scarcely be imagined. Whole provinces were ravaged, and every one of the inhabitants massacred. They were returning, laden with spoil, when the palatine fell upon them a second time, but not with the same success as before. After a most obstinate engagement, he was defeated, and all Poland thus laid open to the ravages of the barbarians. The nobility fled into Hungary, and the peasants sought an asylum amongst rocks and impenetrable forests. Cracow, being thus left entirely defenceless, was soon taken, pillaged, and burnt; after which the barbarians, penetrating into Silesia and Moravia, desolated these countries, destroying Breslau and other cities. Nor did Hungary escape the fury of their barbarity. The king, having given battle to the Tartars, was defeated with great slaughter, and had the mortification to see his capital laid in ashes, and above one hundred thousand of his subjects perish by fire and sword. The arms of the Tartars proved invincible. Nothing could withstand the prodigious force they brought into the field, and the fury with which they fought. Fixing their headquarters on the frontiers of Hungary, they spread their devastations on every side, with a celerity and success that threatened the destruction of the whole empire, as well as that of the neighbouring kingdoms.

Knights of the Teutonic order first called into Poland.

Poland was reduced to this dreadful situation when Boleslas, surnamed the Chaste, obtained the sovereignty. But this, so far from putting an end to the troubles, only superadded a civil war to the other calamities with which the country was afflicted. Boleslas was opposed by his uncle Conrad, the brother of Lesko, who was provoked at becoming the subject of his own nephew. Having assembled a powerful army, he gained possession of Cracow, assumed the title of Duke of Poland, and might possibly have kept possession of the sovereignty, had not his avarice and pride offended equally the nobility and the peasants. Hence they unanimously invited Boleslas, who had fled into Hungary, to return home and head the insurrection which now broke out in every quarter. On his arrival, he was joyfully received in the capital. But Conrad still headed a powerful party; and it is reported that on this occasion the knights of the Teutonic order were first called into Poland, to dispute the pretensions of Boleslas. All endeavours of Conrad, however, proved unsuccessful. He was defeated in two pitched battles, and forced to live in a private situation; though he never ceased to harass his nephew, and make fresh attempts to recover the crown. Of the reign of Boleslas, however, we have little information, except that he made a vow of perpetual continency, and imposed the same on his wife; that he founded nearly forty monasteries; and that after a long reign he died in 1279, having previously adopted Lesko, duke of Cujavia, and procured a confirmation of his choice by the free election of the people.

Poland overrun by the Russians, Tartars, and Lithuanians.

The reign of this last prince was one continued scene of foreign and domestic trouble. On his accession he was attacked by the united forces of Russia and Lithuania, assisted by the Tartars; but he had the good fortune to defeat the confederate barbarians in a pitched battle. By this victory the enemy were obliged to quit the kingdom; but Lesko was so much weakened, that civil dissensions immediately afterwards ensued, and increased to such a degree that he was obliged to fly to Hungary, the common resource of distressed Polish princes. The inhabitants of Cracow alone remained firm in their duty; these brave citizens having stood all the fatigue and danger of a tedious siege, until they were at last relieved by Lesko at the head of a Hungarian army, who defeated the rebels, and restored to his kingdom a legitimate government. But scarcely had he re-ascended the throne when the united forces of the Russians, Tartars, and Lithuanians made a second irruption into Poland, and desolated the country with the most savage barbarity. Their forces were now rendered more terrible than ever by their having along with them a vast number of large dogs trained to join in their attacks. With an army much inferior, however, Lesko obtained a complete victory, the Poles being animated by all the fury of despair. Soon after this, Lesko died, with the reputation of a wise, warlike, but, on the whole, an unfortunate prince.

Uladislas Lokietek.

As this prince died without issue, his crown was contested; a civil war again ensued; and the affairs of the state continued in a very declining condition till the year 1296, when Prezemislas, the duke, resumed the title of king. However, they did not revive in any considerable degree till the year 1305, when Uladislas Lokietek, who had seized the throne in 1300, and afterwards been driven out, was restored. The first transaction of his reign was a war with the Teutonic knights, who, during the recent disturbances, had usurped the greater part of Pomerania. They had been settled in the territory of Culm by Conrad, duke of Mazovia, but soon extended their dominion over the neighbouring provinces, and had even obtained possession of the city of Dantzig, where they massacred a number of Pomeranian gentlemen in cold blood; an atrocity which so terrified the neighbouring towns, that they submitted without a struggle. The knights were commanded by the sovereign pontiff to renounce their conquests; but they set at nought all his thunders, and even suffered themselves to be excommunicated rather than part with their acquisitions. As soon as this happened, the king marched into the territories of the Marquis of Brandenburg, who had pretended to sell to the Teutonic knights a right to those countries, although he had none to them himself. Uladislas next entered the territory of Culm, which he laid waste with fire and sword; and although opposed by the joint forces of the marquis, the knights, and the Duke of Mazovia, he obtained a complete victory, after a desperate and bloody engagement. Without following up the blow, however, he returned to Poland, where he recruited his army; and being reinforced by a body of auxiliaries from Hungary and Lithuania, he dispersed the enemy's forces, and a second time ravaged all the dominions of the Teutonic knights. Had he improved this advantage, he might easily have exterminated the whole order, or at least reduced them so low that they could never again have caused disturbances in the state. But he suffered himself to be soothed and cajoled by the promises which they made, without any design of keeping their engagements, and concluded a treaty under the mediation of the kings of Hungary and Bohemia. In a few months, however, he was convinced of the perfidy of the knights, who not only refused to evacuate Pomerania, as had been stipulated in the treaty, but even endeavoured to extend their usurpations, and for this purpose assembled a very considerable army. Uladislas, enraged at their treachery, once more took the field, and gave them battle with such success, that four thousand knights were left dead on the ground, and thirty thousand auxiliaries killed or taken prisoners. Yet though the king had it once more in his power to destroy the whole order, he satisfied himself with obtaining the territories which had occasioned the war, after which he spent the remainder of his life in tranquillity and peace.

Black Russia conquered by Casimir the Great.

Uladislas was succeeded by his son Casimir III. surnamed the Great. Having in a single campaign subdued the province called Black Russia, he turned his arms against Mazovia, which he overran with great rapidity, and annexed as a province to the crown. He then applied himself to domestic affairs, and was the first who introduced a written code of laws into Poland. He was a most impartial judge, a rigid observer of justice, and the most submissive to the laws of any potentate mentioned in the history of Europe. The only vice with which he is charged is that of incontinence; but even this the clergy declared to be a venial sin, amply compensated by his other virtues, particularly the great liberality which he showed to the clerical order. Casimir was a great patron of industry as well as an eminent legislator, and through his encouragement numbers flocked into his kingdom from various parts of Germany. He fortified many of his chief towns, which he also embellished; whilst colleges, hospitals, churches, and other public buildings, attested alike his genius, his magnificence, and his patriotism. His reign is considered as the golden age of Poland.

Unhappy reign of Louis.

Casimir was succeeded in 1370 by his nephew Louis, king of Hungary; but as the Poles looked upon him as a foreign prince, they were not happy under his administration. Indeed a coldness between this monarch and his people took place even before he ascended the throne; for in the *pacta conventa*, to which the Polish monarchs were obliged to swear, a great number of unusual articles were inserted. This probably was the reason why he left Poland almost as soon as he had been crowned, carrying with him the crown, sceptre, globe, and sword of state, to prevent the Poles from electing another prince during his absence. He left the government in the hands of his mother Elizabeth, who would have been agreeable to the people had she possessed sufficient capacity for government. At that time, however, the state of Poland was too disturbed to be governed by a woman. The country was overrun with robbers and other gangs of villains, who committed the most horrid disorders; the kingdom was likewise invaded by the Lithuanians; the province of Black Russia had revolted; and the land was universally filled with dissension. The Poles, displeased to see their towns occupied by Hungarian garrisons, sent a message to the king, informing him that they thought he had been sufficiently honoured in being elected king of Poland himself, without suffering the kingdom to be governed by a woman and his Hungarian subjects. Upon this Louis raised a numerous army, intending to subdue the refractory spirit of his subjects. His first operations were directed against the Russians, whom he defeated, and again reduced to subjection. He then turned his arms against the Lithuanians, expelled them from the kingdom, and re-established public tranquillity. Instead of being satisfied with this, however, and removing the Hungarian garrisons, he introduced many more, and raised Hungarians to all the chief offices of government. His credit even went so far as to get a successor nominated who was disagreeable to the whole nation, namely, Sigismund, marquis of Brandenburg. After the death of Louis, however, this election was set aside; and Hedwig, daughter of Casimir the Great, was proclaimed queen.

Hedwig marries Uladislas, duke of Lithuania.

This princess married Jagellon, duke of Lithuania, who was converted to Christianity, and baptized by the name of Uladislas. By this marriage, the duchy of Lithuania, as well as the vast provinces of Samogitia and Black Russia, were annexed to the crown of Poland. Such a formidable accession of power excited the jealousy of the Teutonic knights. They were sensible that Uladislas was now bound to undertake the reduction of Pomerania, and revenge all the injuries which Poland had sustained for a great number of years; and from his first accession, considering this monarch as their greatest enemy, they endeavoured to prevent his designs, by effecting a revolution in Lithuania in favour of his brother Andrew. The prospect of success was the greater, as most of the nobility were discontented with the marriage; and Uladislas had proposed to effect a revolution in religion. Two armies, therefore, marched suddenly towards the frontiers of the duchy, which they penetrated; laying waste the whole country, and seizing upon some important fortresses, before the king of Poland had any notice of the matter. As soon as he received advice of these ravages, Uladislas raised forces with the utmost celerity, which he committed to the care of his brother Skirgello; who, having defeated the Teutonic knights, obliged them to abandon all their conquests.

Troubles in Lithuania.

Having secured the tranquillity of Poland, Uladislas visited Lithuania, attended by a great number of the clergy, in order to convert his subjects. This he effected without much difficulty; but he left the care of the duchy to his brother Skirgello, a man of a cruel, haughty temper, and who immediately began to abuse his power. Along with him the king sent his kinsman Vitowda, a prince of a generous, brave, and amiable disposition, to be a check upon his conduct; but the barbarity of Skirgello soon obliged this prince to take refuge amongst the Teutonic knights. For some time, however, he did not assist the knights in their designs against his country; but having in vain applied to the king for protection, he at last joined in the schemes formed by the knights for the destruction of Poland. Entering Lithuania at the head of a numerous army, he took the capital by storm, burned part of it, and destroyed fourteen thousand persons in the flames, besides a great number who were massacred in attempting to make their escape. The upper part of the city, however, was vigorously defended, so that the besiegers were at last obliged to abandon all thoughts of making themselves masters of it, and to content themselves with desolating the adjacent country. The next year Vitowda renewed his attempts upon the city, but with the same want of success; though he got possession of some places of less importance. As soon, however, as an opportunity offered, he came to an accommodation with the king, who conferred on him the government of Lithuania. During the first years of his government, he bestowed great attention on domestic affairs; but at last his impetuous valour prompted him to engage in a war with Tamerlane, after the victory gained by the latter over Bajazet the Turkish emperor. Prior to this time Vitowda had been at war with the neighbouring Tartars, and had been constantly victorious. Uladislas, however, dissuaded him from attacking the whole strength of the nation under such a celebrated commander as Tamerlane; but Vitowda was obstinate in his determination to fight. He encountered an army of four hundred thousand Tartars under Ediga, Tamerlane's lieutenant, with only a tenth part of their number, and the battle continued for a whole day; but at last Vitowda was surrounded by the numbers of his enemy, and in the utmost danger of being cut in pieces. However, he cleared his way with prodigious slaughter on both sides, and came off without a total defeat, having killed a number of the enemy equal to the whole of his own army.

War with the uto-nic k ghts.

During the absence of Vitowda, the Teutonic knights had penetrated into Lithuania, committing everywhere dreadful ravages. On his return he attacked and defeated them, making an irruption into Livonia, to punish the inhabitants of that country for the assistance which they had given to the Teutonic order. This was succeeded by a long series of wars between Poland and Prussia, in which it became necessary for Uladislas himself to take the field. The knights having now got possession of Samogitia, Mazovia, Culm, Silesia, and Pomerania, Uladislas resolved to punish them before they became too powerful; and with this view he assembled an army composed of several different nations. He then penetrated into Prussia; took several towns; and was advancing to Marienburg, the capital of Pomerania, when he was met by the army of the Prussian knights, who determined to hazard a battle. When the engagement began, the Poles were deserted by all their auxiliaries, and obliged to stand the brunt of the battle. But the courage and conduct of their king so animated them, that after a most desperate struggle, they obtained a complete victory; near forty thousand of the enemy being killed in the field, and thirty thousand taken prisoners. This terrible overthrow, however, was less fatal to the affairs of the Prussian knights than might have been expected. Uladislas did not improve his victory, and a peace was concluded upon easier terms than his adversaries had any reason to hope for.

Uladi s VI.

Uladislas V. died in 1435, and was succeeded by his son Uladislas VI., at that time only nine years of age. He had scarcely ascended the throne, when the kingdom was invaded by the Tartars, who defeated the general of the Polish forces; and, committing everywhere dreadful ravages, returned to their own country loaded with booty. A few years afterwards the nation was involved in a war with Amurath, the sultan, who threatened to break into Hungary. But before all things were prepared for the young king taking the field, a strong body of auxiliaries was despatched under John Hunniades, waywode of Transylvania, to oppose the Turks, and likewise to support the election of Uladislas to the crown of Hungary. This detachment surprised the Turkish army near the river Morava, and defeated Amurath with the loss of thirty thousand men; after which Hunniades retook all the places which had been conquered by Amurath, the sultan was forced to sue for peace, and Uladislas was raised without opposition to the crown of Hungary. A treaty was concluded, by which the Turks promised to relinquish their designs upon Hungary, to acknowledge the king's right to that crown, and to give up all their conquests in Bosnia and Servia. This treaty was sealed by mutual oaths; but Uladislas broke it at the persuasion of the pope's legate, who insisted, that now was the time for humbling the power of the infidels, and produced a special commission from the pope, absolving the king from the oath he had taken at the late treaty. The result of this perfidy was, that Uladislas was entirely defeated and killed at Varna, and the greater part of his army cut in pieces.

Casimir IV.

Teutonic knights subdued.

Uladislas VI. was succeeded by Casimir IV. in whose reign the Teutonic knights were subdued, and obliged to yield up the territories of Culm, Michlow, and the duchy of Pomerania, together with the towns of Elbing, Marienburg, Talkmith, Schut, and Christburg, to the crown of Poland. On the other hand, the king restored to them all the other conquests he had made in Prussia; granted a seat in the Polish senate to the grand-master; and endowed him with other privileges, on condition that, six months after his accession, he should do homage for Prussia, and take an oath of fidelity to the king and republic. This success raised the spirits of the Polish nation, which had drooped ever since the battle of Varna. The Diet did not, however, think proper to renew the war against the Turks.

Crowns of Bohemia and Hungary united to that of Poland.

About this time the crown of Bohemia having become vacant, and the people being desirous of being governed by one of the princes of Poland, the barons were induced to bestow the crown upon Uladislas, eldest son of Casimir, in opposition to the intrigues of the king of Hungary. Not satisfied with this acquisition, however, Uladislas took advantage of the dissensions in Hungary, in order to unite that crown to his own, which he also effected, and thereby greatly augmented his power, though not the happiness of his people. Numerous foreign expeditions had exhausted the treasury, and oppressed the peasants with taxes; the gentry were greatly diminished by a number of bloody engagements; agriculture was neglected, and the country almost depopulated. But before a proper remedy could be applied for these evils, Casimir died in 1492. In the reign of this prince, the deputies of the provinces first appeared at the Diet, and assumed to themselves the legislative power; all laws before that time having been framed by the king in conjunction with the senate.

Exploits of Sigismund.

During the succeeding reigns of John Albert and Alexander, the affairs of Poland fell into decline, the kingdom being harassed by continual wars with the Turks and Tartars. But they were retrieved by Sigismund I. who ascended the throne in 1507. This monarch, having reformed some internal abuses, set about rendering the kingdom as formidable as it had formerly been. He first quelled an insurrection which broke out in Lithuania; after which, he drove the Walachians and Moldavians out of Black Russia, and defeated the Russians in a pitched battle, with the loss of thirty thousand men. In this engagement he was obliged to cause his cavalry to swim across the Borysthenes in order to begin the attack, whilst a bridge was preparing for the infantry. These orders were executed with astonishing celerity, notwithstanding the rapidity of the stream, the steepness of the banks, and the enemy's opposition. The onset was led by the Lithuanians, who were directed to retreat gradually, with a view of drawing the enemy within reach of the cannon. This the Russians mistook for a real flight; and as they were pursuing with eagerness, Sigismund opened his line to the right and left, pouring in grape-shot from the artillery with dreadful success. The Russian general, and several noblemen of the first distinction, were taken prisoners, whilst the whole loss of the royal army did not amount to three hundred men.

After this victory, the king turned his arms against the Teutonic knights, who had elected the Marquis of Brandenburg as their grand-master; whilst this prince not only refused to acknowledge the sovereignty of the crown of Poland, but even invaded the Polish territories. Sigismund marched against him, and gained possession of several important places in Brandenburg; but as he was pursuing his conquests, the marquis, reinforced by fourteen thousand Germans led by the Duke of Schonenburg, ventured to lay siege to Dantzig, after having ravaged the neighbouring country. The Dantzigers, however, defended themselves so bravely, that the besiegers were soon obliged to relinquish their enterprise; whilst in their retreat they were attacked by a strong detachment of Polish cavalry, who made prodigious havoc amongst them, compelling the wretched remains to take shelter in Pomerania, where they were massacred by the peasants. Soon after this the marquis was obliged to submit to the clemency of the conqueror. To secure him in his interest, however, Sigismund granted him half the province of Prussia as a secular duke, dependent on the crown of Poland.

In the reign of Sigismund, the kingdom of Poland may be considered as having attained its greatest pitch of glory. This monarch possessed, in his own person, the republic of Poland, the great duchies of Lithuania, Smolensko, and Saveria, besides vast territories lying beyond the Euxine and the Baltic; whilst his nephew Louis possessed the kingdoms of Bohemia, Hungary, and Silesia. But this glory received a sudden check in 1548, by the defeat and death of Louis, who perished in a battle fought with Solyman the Great, sultan of the Turks. The daughter of this prince married Ferdinand of Austria, an alliance by which the dominions of Hungary, Bohemia, and Silesia, became inseparably connected with the hereditary dominions of the Austrian family. This misfortune is believed to have hastened the death of Sigismund; though, being then in the eighty-fourth year of his age, he could not, by the ordinary course of nature, have lived long. He did not, however, survive the news many months, but died of a lingering disorder, leaving behind him the character of a complete general, an able politician, a good prince, and one of the strongest men in the north.

Sigismund Augustus.

Sigismund Augustus, who succeeded his father Sigismund I. proved also a very fortunate prince. At that time the most violent and bloody wars were carrying on in Germany, and indeed throughout other parts of Europe, on account of religion; but Sigismund wisely avoided interfering in these disputes. He would not admit into his dominions any of those divines who were taxed with holding heterodox opinions, nor even allow his people the liberty of corresponding with them; yet he never persecuted, nor employed any other means for the preservation of the state than those of a well-conducted and regular policy. Instead of disputing with his subjects about speculative opinions, Sigismund applied himself diligently to the reforming of abuses, enforcing the laws, enriching the treasury, promoting industry, and redeeming the crown-lands where the titles of the possessors appeared illegal. Out of the revenue recovered in this manner he raised a formidable standing army without laying any additional tax upon his subjects; and though he preferred peace to war, he was always able to punish those who offered indignities to his person or his crown.

His knowledge of the art of war was soon tried in a contest with the Russians, who, encouraged by the disputes which had subsisted between the Teutonic knights and the archbishop of Riga, cousin of Sigismund, had made an irruption into Livonia. The province was at that time divided between the knights and the prelate; and the Russians, under pretence of assisting the former, had seized great part of the dominions of the latter. The archbishop had recourse to his kinsman the king of Poland, who, after fruitless efforts to accommodate matters, marched towards the frontiers of Livonia with an army of a hundred thousand men. The knights were in no condition to resist such a formidable power; and therefore, deserting their allies, they put themselves under the protection of the king of Poland. But the czar, John Basilides, though deserted by the knights, did not lose his courage; nay, he even insolently refused to return any answer to the proposals of peace made by Sigismund. His army consisted of three hundred thousand men, with whom he imagined himself able to reduce all Livonia, in spite of the utmost efforts of the king of Poland; but having met with some checks in that quarter, he directly invaded Poland with his whole army. At first he carried everything before him; but the Poles soon made a vigorous opposition; and the Russians, though everywhere defeated, still continued their incursions, which Sigismund at last revenged by invading Russia in his turn.

Extinction of the house of Jagellon.

These mutual desolations and ravages at last made both parties desirous of peace, and a truce for three years was agreed on; but during the continuance of the armistice the king of Poland died, and with him was extinguished the house of Jagellon, which had governed Poland for nearly two hundred years. On the death of Sigismund, Poland became a prey to intestine divisions; and intrigues were set on foot at the courts of Vienna, France, Saxony, Sweden, and Brandenburg, each of them endeavouring to establish a prince of their own nation on the throne of Poland. The result of all this was, that the kingdom became one universal scene of corruption, faction, and confusion. The members of the Diet consulted only their own interest, and were ready on every occasion to sell themselves to the best bidder. The Protestants had by this time got a considerable footing in the kingdom, and thus religious disputes were intermingled with political ones. One good effect, however, flowed from this confusion. A law was passed, by which it was enacted that no difference in religious opinions should occasion any contention amongst the subjects of the kingdom; that all the Poles, without discrimination, should be capable of holding public offices and trusts under the government; and that the future kings should swear expressly to cultivate the internal tranquillity of the realm, and to cherish without distinction their subjects of all persuasions.

Duke of Anjou chosen king.

Whilst the candidates for the throne were severally attempting to support their own interest in the best manner they could, John Crasoski, a Polish gentleman of great merit, but diminutive stature, had just returned from France, whither he had travelled for improvement. His humour, wit, and diverting size, had rendered him universally agreeable at the court of France, and in a particular manner engaged the esteem of Catharine de' Medicis, which the little Pole had the address to make use of for his own advantage. He owed many obligations to the Duke of Anjou, whom, out of gratitude, he represented in such favourable terms, that the Poles began to entertain thoughts of making him their king. These sentiments were confirmed and encouraged by Crasoski, who returned into France by order of several leading men in Poland, and acquainted the king and queen-mother that nothing was wanting except the formality of an embassy to procure the crown for the Duke of Anjou, almost without opposition. Charles IX. king of France, at that time also promoted the scheme; being jealous of the Duke of Anjou's popularity, and willing to have him removed to as great a distance as possible. The parties accordingly came to an agreement, in which it was stipulated that the Duke of Anjou should maintain the laws, liberties, and customs of the kingdom of Poland, and of the grand duchy of Lithuania; that he should transport all his effects and annual revenues in France into Poland; that the French monarch should pay the late king Sigismund's debts; that he should maintain a hundred young Polish gentlemen at his court, and fifty in other places; that he should send a fleet to the Baltic to assist Poland against the Russians; and, lastly, that Henry should marry the Princess Anne, sister of the late king Sigismund, though this article Henry refused to ratify till his return to Poland. Everything being thus settled, the young king quitted France, attended by a splendid retinue, and was accompanied by the queen-mother as far as Lorraine. He was received by his subjects on the frontiers of Poland, and conducted to Cracow, where he was soon afterwards crowned.[1] The affections of the Poles were soon engaged by the youth and accomplishments of Henry; but scarcely had he been seated on the throne, when, by the death of Charles IX., he became heir to the crown of France. Being informed of this by repeated messages from Catharine, he repented his having accepted the crown of Poland, and resolved to leave it for that of France. But being sensible that the Poles would oppose his departure, he kept his intentions secret, and watched an opportunity of stealing out of the palace in disguise during the night-time. The Poles, as might well be expected, were irritated at being thus abandoned, from the mere motive of interest, by a prince whom they had so much loved and honoured. Parties were despatched after him by different roads; and Zamoski, a nobleman who headed one of these parties, overtook him some leagues distant from Cracow. All the prayers and tears of that nobleman, however, could not prevail on Henry to return; he rode post to Vienna, and then passed into France by the way of Italy.

He is dep ed.

In the mean time the Poles were so much exasperated against Henry and his nation, that all the French in Cracow would have been massacred if the magistrates had not placed guards in the streets. Henry, however, had foreseen the consequences of his flight, and therefore endeavoured to apologise for his behaviour. But nothing could satisfy the Poles, who now acquainted their king, that if he did not immediately return, they would be obliged to divest him of the royal dignity, and to choose another sovereign. Henry began to excuse himself on account of the wars in which he was engaged, and promised to send men of unexceptionable integrity to govern Poland till he should return. But no excuses were accepted; and on the 15th of July 1575, he was in full Diet solemnly divested of the regal dignity, and the throne declared vacant.

Ste en Bat y cho n king

After the deposition of Henry, commotions and factions again occurred, but the contending parties were now reduced to two; one who supported the interest of Maximilian, emperor of Germany; and the other, who were for electing the Princess Anne, and marrying her to Stephen Batory, prince of Transylvania. The latter prevailed through the courage of one gentleman, who, in imitation of the power assumed by the Roman tribunes, stood up in the full senate, and opposed the proclamation of Maximilian, declaring that his election was violent and illegal. In this situation of affairs, it was obvious that strength and celerity must determine which election was legitimate; and both parties wrote to the princes whose cause they had espoused, entreating them to hasten with all possible expedition to take possession of the throne. Batory proved the more alert; for whilst Maximilian was disputing about certain conditions which the Poles required for the security of their privileges, he entered Poland, married the princess, and was crowned on the 1st of May 1576. No opposition was made to the authority of Batory, except by the inhabitants of Dantzig, who adhered to the interest of Maximilian, even after he was dead, and had the presumption to demand from the king an oath acknowledging their absolute freedom and independence. Batory referred them to the senate, declaring that he had no right to give up the privileges of the republic; but he admonished the citizens to avoid all occasion of a civil war, which must necessarily terminate in their disadvantage. The obstinate citizens, however, construing the king's lenity into fear, shut the gates against the ambassador, seized upon the fortress of Grebin, and published a manifesto against the king and the republic. The king, incensed at these proceedings, marched against Grebin, retook the castle, and ravaged certain territories belonging to the people of Dantzig; who, on the other hand, retaliated by burning to the ground a monastery named Oliva, to prevent the Poles from taking possession of so important a position. Batory now renewed overtures of accommodation, but to no purpose. The people of Dantzig were deaf to these proposals; and it was not until after suffering severely that they were at length induced to submit.

Cruelty of the Russians.

The war with Dantzig had no sooner been ended than the king directed his whole strength against the czar of Muscovy, who had laid siege to Revel, and made himself master of several important cities in Livonia. The czar behaved everywhere with the greatest cruelty, slaughtering without distinction all who were able to bear arms, and abandoning the women and children to the brutality of the Tartars who served in his army. The Russians were allowed to proceed in this manner till the whole province of Livonia, excepting Riga and Revel, had suffered the barbarities of this insulting conqueror. But at length, in 1578, a body of forces was despatched into the province; the towns of Wender and Dwinaburg were surprised; and an army sent by the czar to surprise the former was defeated. At this time the Muscovites were not the only enemies who opposed the king of Poland and oppressed Livonia. That unhappy province was also invaded by the Swedes, who professed themselves to be enemies equally to both parties, and who in cruelty were scarcely inferior to the Russians themselves. The king, however, was not daunted by the number of his adversaries. Having made great preparations, and called to his assistance Christopher, prince of Transylvania, with all the standing forces of that country, he took the field in person against the Muscovites, and laid siege to Polocz, a town of great importance, situated on the river Dwina. The Russians no sooner heard of the approach of the Polish army than they resolved to put all the citizens to death, thinking by this means to strike terror into the enemy. When Batory came near the town, the most shocking spectacle presented itself. The river appeared dyed with blood, and a vast number of human bodies, fastened to planks, and terribly mangled, were carried down the stream. But this barbarity, instead of intimidating the Poles, irritated them to such a degree that nothing could resist them. Finding that their cannon made little impression upon the walls of the city, which were constructed of wood, they advanced to the assault with burning torches in their hands, and would soon have reduced the fortifications to ashes, had not a violent storm of rain prevented them. The design, however, was put in execution as soon as the rain slackened; and the Russian barbarians were obliged to surrender at discretion. It reflects the highest honour on Batory, that, notwithstanding the dreadful instances of cruelty which he had before his eyes, he did not suffer his soldiers to retaliate. Indeed the atrocities committed by the Russians on this occasion seem almost to have authorized any revenge that could possibly have been taken.

---

[1] Henry of Valois, afterwards Henry III. of France, when he was elected king of Poland, was the first who swore to the celebrated *pacta conventa*, a document containing certain obligations on the part of the king in regard to the liberties of the nation.

Russia ravaged by Batory.

After the reduction of Polocz, Batory continued the war, and with great success. Two detachments from the army penetrated the enemy's country by different roads, wasted all before them to the gates of Smolensko, and returned with the spoils of two thousand villages which they had pillaged and destroyed. In the mean time the Swedes and Poles thought proper to come to an accommodation; and though John, king of Sweden, was at that time prevented from bearing his share of the war, yet Batory reduced such a number of cities, and committed such devastations, in the Russian territories, that the czar was obliged to sue for peace, which he obtained on condition of relinquishing Livonia, after having thrown away the lives of more than four hundred thousand of his subjects in attempting to conquer it.

Batory being thus freed from a most destructive and cruel war, applied himself to the internal government of his kingdom. He regulated the Polish cavalry in such a manner that they became formidable to the Turks and other neighbouring nations; and this is the military establishment to which the Poles have given the name of *quartienne*, because a fourth part of the revenue was employed in supporting them. Batory sent this body of cavalry towards the frontiers of Tartary, to check the incursions of the barbarians inhabiting that country; and by its means the Ukraine, a vast tract of desert country, was filled with flourishing towns and villages, and became a strong barrier against the Turks, Tartars, and Russians. The last memorable action of Batory was his attaching to Poland the Cossacks, whom he civilized and instructed in the arts of war and peace. All kinds of manufactures at that time known in Poland were likewise established amongst the Cossacks; the women were employed in spinning and weaving woollen cloths, whilst the men were taught agriculture, and other arts proper for masculine cultivation.

Whilst Batory was employed in this manner, the Swedes broke the convention into which they had entered with Poland, and were on the point of obtaining possession of Riga. To this, indeed, Batory himself had given occasion, by attempting to impose the Catholic religion upon the inhabitants, after having promised them entire liberty of conscience; a proceeding which so irritated them, that they revolted, and were on the point of admitting a Swedish garrison into the city, when the king became informed of what was going forward. He resolved to take a most exemplary vengeance on the inhabitants of Riga; but before he could execute his intention, he died, in 1586, the fifty-fourth year of his age, and tenth of his reign.

Consequences of Batory's death. Sigismund III.

The death of Batory involved Poland in fresh troubles. Four candidates appeared for the crown; the princes Ernest and Maximilian of the house of Austria, Sigismund prince of Sweden, and Theodore czar of Muscovy. Each of these had a separate party; but Sigismund and Maximilian managed matters so cleverly, that in 1587 both of them were elected. The result was a civil war, in which Maximilian was defeated and taken prisoner; and thus without opposition Sigismund III., surnamed Vasa, became master of the throne of Poland. He waged a successful war with the Tartars, and was otherwise prosperous; but though he succeeded to the crown of Sweden, he found it impossible for him to retain both kingdoms, and he was formally deposed from the Swedish throne. In 1610 he conquered Russia, and placed his son on the throne of that country; but the Polish conquests of that country have always been short-lived. Accordingly, the young prince was soon afterwards deposed; and the Russians not only regained their liberty, but began to make encroachments on Poland itself. A very unfortunate war also took place with Sweden, which was now governed by the great Gustavus Adolphus; but the particulars of that contest, with the other exploits of that renowned warrior, are elsewhere related. At last Sigismund, worn out with cares and misfortunes, died in 1629.

Uladislas VII.

After Sigismund's death the affairs of Poland seemed to revive a little under Uladislas VII., who obliged the Russians to sue for peace, and Sweden to restore some of her conquests; but an attempt being made to abridge the liberty of the Cossacks, they revolted, and gave the Poles several terrible defeats; nor did the war terminate in the lifetime of Uladislas, who died in 1648. His successor, John Casimir, concluded a peace with these dangerous enemies; but the war was soon after renewed; and whilst the kingdom was distracted between the hostility of the Cossacks and the discontents of its own inhabitants, the Russians took the opportunity of invading and pillaging Lithuania.

Poland subdued by Charles Gustavus.

In a little time afterwards, the whole kingdom was subdued by Charles Gustavus, successor to Christina, queen of Sweden. Happily for Poland, however, a rupture took place between the courts of Sweden and Copenhagen, and the Poles were thereby enabled to drive out the Swedes in 1657. This was succeeded by civil wars and contests with Russia, which so much vexed the king that he resigned the crown in 1668. For two years after the resignation of Casimir, the kingdom was filled with confusion; but on the 17th of September 1760, one Michael Koributh Wisnowieçki, collaterally descended from the house of Jagellon, though in a very mean situation at that time, was chosen king. His reign continued only for three years, during which time John Sobieski, a celebrated Polish general, gave the Turks a dreadful overthrow, though their army consisted of more than three hundred thousand men; and if this blow had been followed up, the Cossacks would not only have been entirely subdued, but very advantageous terms might have been obtained from the sultan. Of that vast multitude of Turks, no more than fifteen thousand made their escape, the rest being all either killed or taken. However, the Polish soldiers, being only bound by the laws of their country to stay a certain time in the field, refused to pursue this signal victory, and suffered the king to make peace on any terms he could procure.

John Sobieski retrieves the affairs of the Poles.

Wisnowieçki died before the news of this transaction reached Cracow; and after his death a new scene of confusion ensued, till at last the fortune of John Sobieski prevailed, and he was elected king of Poland in 1674. A most magnanimous and heroic prince, it was he who, by his valour and good conduct, retrieved the affairs of Poland, and entirely checked the progress of the Turks westward. These barbarians were everywhere defeated; but notwithstanding his great qualities, Poland was now so thoroughly corrupted, and pervaded by such a spirit of disaffection, that the latter part of this monarch's reign was involved in troubles, through the ambition and contention of some powerful noblemen. Sobieski died in 1696, and with him the glory of Poland descended into the tomb.

Most violent contests took place about the succession, but the recital of these would far exceed our limits. At last Frederic Augustus, elector of Saxony, prevailed; but as some of the most essential ceremonies were wanting in his coronation, because the primate, who was in an opposite interest, would not perform them, he found it extremely difficult to keep his subjects in proper obedience; and, to add to his misfortunes, having engaged in a league with Denmark and Russia against Sweden, he was attacked with irresistible fury by Charles XII. Though Augustus had not been betrayed, as indeed he almost always was, he was by no means a match for the ferocious Swede. The particulars of this war, however, as they form great part of the exploits of that northern hero, more properly fall to be related under the head of Sweden. Here, therefore, we shall only observe, that Augustus was reduced to the humiliating necessity of renouncing the crown of Poland on oath, and even of congratulating his rival Stanislas upon his accession to the throne. But when the power of Charles was broken by his defeat at Pultowa, the fortune of Augustus again prevailed; Stanislas was driven out; and the former, being absolved from his oath by the pontiff, resumed possession of the throne of Poland.

De ne- rac f the Po .

Since that time the Polish nation has made no figure, except in the history of political iniquity. Surrounded by great and ambitious powers, it has sunk under the pressure, and now scarcely exists as a nation. On the 5th of October 1763, Augustus III., elector of Saxony and king of Poland, died, and was succeeded by Count Poniatowski, a Polish grandee, who, on the 7th of September 1764, was proclaimed king by the name of Stanislas Augustus, and crowned on the 25th of November the same year. During the interregnum which took place between the death of Augustus III. and the election of Stanislas, a decree had been passed by the convocation-diet of Poland, with regard to the Dissidents, as they were called, or dissenters from the Catholic faith, by which they were prohibited the free exercise of their religion, and excluded from all offices and places under the government. On this occasion several of the European powers interposed, and the courts of Russia, Prussia, Great Britain, and Denmark, tendered remonstrances to the Diet; but, notwithstanding these, the decree was confirmed by the coronation-diet held soon after the king's election.

Int e- ren of fore pow s in beha of the ssi- dent

On the 6th of October 1766, an ordinary Diet was assembled. Here declarations from the courts above mentioned were presented to his Polish majesty, requiring the re-establishment of the Dissidents in their civil rights and privileges, and the peaceable enjoyment of their modes of worship secured to them by the laws of the kingdom, which had been observed for two centuries. These privileges, it was alleged, had been confirmed by the treaty of Oliva, concluded by all the northern powers, and could not now be altered except by the consent of all the contracting parties. The Catholic party contended strongly for a confirmation of some decrees against the Dissidents, made in the years 1717, 1723, and 1736. The deputies from the foreign powers replied, that those decrees had passed in the midst of intestine troubles, and were contradicted by the formal protestations and express declarations of those powers. At last, after a violent contest, the matter was referred to the bishops and senators for their opinion; and upon a report from them, the Diet came to a resolution that they would maintain the Dissidents in all the rights and prerogatives to which they were entitled by the laws of their country and by treaties; and that as to their complaints with regard to the exercise of their religion, the college of archbishops and bishops, under the direction of the prince primate, would endeavour to remove all those difficulties in a manner conformable to justice and charity. In the mean time, the court of Russia, resolved to enforce her remonstrances, marched a body of troops to within a few miles of Warsaw. These resolutions of the Diet were by no means agreeable to the Dissidents. The latter dated the beginning of their sufferings from the year 1717. Referring their grievances to the archbishops and bishops was looked upon as a measure the most unreasonable that could be imagined, as that body of men had always been their opponents, and in fact the authors of the evils which had befallen them. When matters came to be considered in this view, an additional body of Russians, to the number of about fifteen thousand, entered Poland.

Cons quen of this i er- feren

The Dissidents, being now pretty sure of the protection of foreign powers, entered, on the 20th of March 1767, into two confederacies, at Thorn and Sluck. One of these was signed by the Dissidents of Great and Little Poland, and the other by those of the grand duchy of Lithuania. The purpose of these confederacies was, an engagement to exert themselves in the defence of their ancient privileges, and the free exercise of their religion; professing at the same time the utmost loyalty to the king, and resolving to send to him a deputation to implore his protection. They even invited those of the Catholic communion, and all true patriots, to unite with them in maintaining the fundamental laws of the kingdom, the peace of religion, and the rights of men in society. They also claimed, by virtue of public treaties, the protection of the powers who were guarantees of their liberties, namely, Russia, Sweden, Great Britain, Denmark, and Prussia. And they protested, that they had no intention of acting to the detriment of the Roman Catholic religion, which they duly respected, but only asked liberty for their own, and the re-establishment of their ancient rights. The three cities of Thorn, Elbing, and Dantzig, acceded to the confederacy of Thorn on the 10th of April; as did the duke and nobles of Courland to that of Sluck on the 15th of May. In the mean time the empress of Russia and the king of Prussia continued to issue forth new declarations in favour of the Dissidents; and the Russian troops in Poland were gradually augmented to thirty thousand men. Great numbers of other confederacies were also formed in different parts of the kingdom; but these at first took little part in the affair of the Dissidents. They complained chiefly of the administration of public affairs, in which they alleged that innovations had been introduced, and were therefore for some time called Confederations of Malcontents. All these confederacies published manifestos, in which they recommended to the inhabitants to receive and treat the Russian troops as the defenders of the liberties of Poland.

General confederacy.

The different confederacies of malcontents formed in the twenty-four districts of Lithuania united at Wilna on the 22d of June; and that general confederacy re-established Prince Radzivil, who had married the king's sister, in his liberty, estates, and honour, of which he had been deprived in 1764 by the states of that duchy. On the 23d of June Prince Radzivil was chosen grand marshal of the general confederacy of all Poland, which then began to be called the National Confederacy, and was said to be composed of seventy-two thousand noblemen and gentlemen. The general confederacy now took such measures as appeared most proper for strengthening their party. They sent to the several waywodes of the kingdom, requiring that all the gentlemen who had not signed the confederacy should do it immediately; that all the courts of justice should subsist as formerly, but not judge any of the confederates; that the marshals of the crown should not pass any sentence without the participation of at least four of the confederates; and that the marshals of the crown and the treasurers should be immediately restored to the possession of their respective rights. In the mean time the Catholic party were not idle. The bishop of Cracow sent a letter to the Diet assembled at Warsaw on the 13th of August, in which he exhorted them to arm their nuncios with courage, by giving them orthodox and pious instructions, that they might not grant the Dissidents new advantages beyond those which were secured to them by the constitutions of the country and the treaties with foreign powers. The pope also sent briefs to the king, the great chancellor, the nobility, the bishops of the kingdom, and to the prince primate, with such arguments and exhortations as were thought most calculated to ward off the impending danger. Councils in the mean time were frequently held at the bishop of Cracow's palace, where all the prelates at Warsaw assembled. On the 26th of September 1767 the confederacy of Dissidents was united with the general confederacy of malcontents in the palace of

Prince Radzivil, who on that occasion expressed great friendship for the Dissidents. In a few days afterwards the Russian troops in the capital were reinforced, and a considerable body of them was posted at about five miles distance.

Tumults in the Diet.

On the 5th of October an extraordinary Diet was held. But the affair of the Dissidents met with such opposition, that it was thought necessary to adjourn the meeting till the 12th, during which interval every expedient was used to gain over those who opposed Prince Radzivil's plan. This was, to appoint a commission furnished with full power to enter into conference with Prince Repnin, the Russian ambassador, concerning the affairs of the Dissidents. But notwithstanding all the pains taken, the meeting of the 12th proved exceedingly tumultuous. The bishops of Cracow and Kiow, with some other prelates, and several magnates, declared that they would never consent to the establishment of such a commission; and at the same time they spoke with more vehemence than ever against the pretensions of the Dissidents. Some of the deputies replied with great warmth; and this occasioned such animosities, that the meeting was again adjourned till the 16th.

Violent proceedings of the Russians.

On the 13th the bishops of Cracow and Kiow, the palatine of Cracow, and the starost of Domski, were carried off by Russian detachments. The crime alleged against them, in a declaration published next day by Prince Repnin, was, that they had been wanting in respect to the dignity of the empress of Russia, by attacking the purity of her intentions towards the republic; though she was resolved to continue her protection and assistance to the general confederacy united for preserving the liberties of Poland, and correcting all the abuses which had been introduced into the government of that country.

Confederacy of Bar.

It was probably owing to this violent proceeding of the Russians that Prince Radzivil's plan was at last adopted, and several new regulations were made in favour of the Dissidents. These innovations, however, soon produced a civil war, which at last ended in the ruin of the kingdom. In the beginning of the year 1768, a new confederacy was formed in Podolia, a province bordering on Turkey; it was afterwards called the Confederacy of Bar, and the intention of it was to abolish, by force of arms, the new constitutions, particularly those in favour of the Dissidents. The members of the new confederacy likewise expressed great indignation at the carrying away the bishops of Cracow, Kiow, and others, and still detaining them in custody.

Podolia was reckoned the fittest place for the purpose of the confederates, who imagined that the Russians could not attack them there without giving umbrage to the Ottoman court. Similar confederacies, however, were quickly entered into throughout the kingdom. The clergy excited all ranks of men to exert themselves in defence of their religion; and so effectual did their exhortations prove, that even the king's troops could not be trusted to act against these combinations. The empress of Russia threatened the new confederates as disturbers of the public tranquillity, and declared, that if they persisted, her troops would act against them. It was some time, however, before the Russian troops were considerably reinforced; nor did they at first seem inclined to act with the vigour that they might have exerted. A good many skirmishes soon occurred between the contending parties, in which the confederates were for the most part defeated. In one of these encounters, the latter being worsted, and hardly pressed, a number of them passed the Dniester and took refuge in Moldavia. This province had formerly belonged to Poland, but was now subject to the grand signior. The Russians, however, pursued their enemies into Moldavia; but in order to prevent any offence being taken by the Porte, Prince Repnin wrote to the Russian resident at Constantinople, that the conduct of the Russian colonel who commanded the party was quite contrary to the orders of his court, and that he would therefore be dismissed.

War between this confederacy and the Russians.

Great cruelty was in the mean time exercised against the Dissidents where there were no Russian troops to protect them. Towards the end of October 1768, Prince Martin Lubomirski, one of the southern confederates, who had been driven out of Poland, and had taken shelter with some of his adherents amongst the mountains of Hungary, caused a manifesto to be posted up on several of the churches of Cracow, in which he invited the nation to a general revolt, assuring them of the assistance of the Ottoman Porte, with whom he pretended to have concluded a treaty. The unhappy kingdom of Poland became the first scene of this war, and in a short time it was reduced to the most deplorable situation. In the end of the year 1768, the peasants of the Greek faith in the Ukraine took up arms, and committed the greatest ravages, having, as they pretended, been threatened with death by the confederates unless they would become Roman Catholics. Against these insurgents the Russians employed their arms, and made great numbers of them prisoners. The rest took refuge amongst the Haidamacks, by whom they were soon joined, and in the beginning of 1769 they entered the Ukraine, committing everywhere the most horrid massacres. Here, however, they were at last defeated by the Polish troops, at the same time that several of the confederacies in Poland were severely chastised. Soon afterwards, the khan of the Crim Tartars having been repulsed with loss in an attempt on Servia, entered the Polish territories, where he left frightful marks of his inhumanity; which, with the cruelties exercised by the confederates, induced the Polish Cossacks of Braclau and Kiovia, amounting to near thirty thousand effective men, to join the Russians, in order to defend their country against these destroyers. Matters continued much in the same state during the rest of the year 1769; and in 1770 skirmishes frequently occurred between the Russians and confederates, in which the latter were almost always worsted; but they took care to revenge themselves by the most barbarous cruelties on the Dissidents, wherever they could find them. In 1770, a considerable number of the confederates of Bar, who had joined the Turks, and been excessively ill used by them, came to an accommodation with the Russians, who took them under their protection upon very moderate terms. In the mean time agriculture had been so much neglected, that the crop of 1770 proved deficient. This encouraged a number of desperadoes to associate, who, under the denomination of Confederates, were guilty of still greater excesses than those who had been under some kind of regulation; and thus a great part of the country was at last reduced to a mere desert, the inhabitants being either exterminated, or carried off to stock the remote Russian plantations.

New confederacies

In the year 1771, the confederacies, which appeared to have been extinguished, sprang up afresh, and increased to a great degree. This was occasioned by their having been secretly encouraged and supplied with money by France. A great number of French officers also engaged as volunteers in their service; and having introduced discipline amongst their troops, they acted with greater vigour than formerly, sometimes proving more than a match for their enemies. But these gleams of success served only to light them on to their ruin. The Russians were reinforced and properly supported. The Austrian and Prussian troops entered the country, advancing on different sides; and in a short time the confederates found themselves entirely surrounded by enemies, who seemed to have nothing less in view than an absolute conquest of the country, and sharing it amongst themselves.

Attem assassi the king

Before matters came to this crisis, however, the confederates had formed a design of assassinating the king, on account of his supposed attachment to the Dissidents. A Polish nobleman, named Pulaski, a general in the army of the confederates, was the person who planned the enterprise; and the conspirators who carried it into execution were about forty in number, headed by three chiefs, named respectively Lukawski, Strawenski, and Kosinski. These chiefs had been engaged and hired for the purpose by Pulaski, who obliged them to swear in the most solemn manner, either to deliver the king alive into his hands, or, in case that was found impossible, to put him to death. On the 2d of September they obtained admission into Warsaw, unsuspected and undiscovered. On Sunday night, the 3d of September 1771, a few of these conspirators remained in the skirts of the town; but the others repaired to the place of rendezvous, the street of the Capucins, where his majesty was expected to pass about his usual hour of returning to the palace. The king had been to visit his uncle Prince Czartoryski, grand chancellor of Lithuania, and was on his return from thence to the palace between nine and ten o'clock. He was in a coach, accompanied by at least fifteen or sixteen attendants, besides an aide-de-camp in the carriage. Scarcely was he at the distance of two hundred paces from Prince Czartoryski's palace, when he was attacked by the conspirators, who commanded the coachman to stop on pain of instant death. They fired several shots into the carriage, and almost all the other persons who preceded and accompanied his majesty were dispersed; the aide-de-camp having also abandoned him, and attempted to conceal himself by flight. Meanwhile the king had opened the door of his carriage with the design of effecting his escape under cover of the night, which was extremely dark, when the assassins seized him by the hair, exclaiming in Polish, "We have thee now; thy hour is come." One of them discharged a pistol at him, so very near that he felt the heat of the flash; whilst another cut him across the head with his sabre, which penetrated to the bone. They then laid hold of him by the collar, and mounting on horseback, dragged him along the ground between their horses at full gallop for nearly five hundred paces through the streets of Warsaw. But finding that he was incapable of following them on foot, and that he had already almost lost his respiration from the violence with which they had dragged him, they set him on horseback, and then redoubled their speed for fear of being overtaken. When they came to the ditch which surrounds Warsaw, they obliged him to leap his horse over the obstacle.

They had no sooner crossed the ditch than they began to rifle the king, tearing off the order of the Black Eagle of Prussia, which he wore round his neck, and the diamond cross attached to it. Having thus plundered him, a great number of the assassins retired, probably intending to notify to their respective leaders the success of their enterprise, and the king's arrival as a prisoner. Only seven remained with him, of whom Kosinski was the chief. The night was exceedingly dark; they were absolutely ignorant of the way; and, as the horses could not keep their legs, they obliged his majesty to follow them on foot. They continued to wander through the open meadows, without following any certain path, and without getting to any distance from Warsaw. After some time, they again mounted the king on horseback, two of them holding him on each side; and in this manner they were proceeding, when his majesty, finding they had taken the road which led to a village called Burakow, warned them not to enter it, because there were some Russians stationed in that place, who might probably attempt to rescue him. From the time they had passed the ditch, they repeatedly demanded of Kosinski, their chief, if it was not yet time to put the king to death; and these demands were reiterated in proportion to the obstacles and difficulties they encountered, till they were suddenly alarmed by a Russian patrole or detachment. Instantly holding council, four of them disappeared, leaving the king with the other three, who compelled him to walk on. Scarcely a quarter of an hour after, a second Russian guard challenged them anew. Two of the assassins then fled, and the king remained alone with Kosinski. His majesty, exhausted with the fatigue which he had undergone, implored his conductor to stop, and suffer him to take a moment's repose. Kosinski refused, at the same time informing him, that beyond the wood they should find a carriage. They continued their walk till they came to the door of the convent of Bielany. Kosinski appeared lost in thought. "I see you are at a loss which way to proceed," said the king. "Let me enter the convent of Bielany, and do you provide for your own safety." "No," replied Kosinski; "I have sworn."

They proceeded till they came to Mariemont, a small palace belonging to the house of Saxony, not above half a league from Warsaw. Here Kosinski betrayed some satisfaction at finding where he was, and the king still demanding an instant's repose, he at length consented. They sat down together on the ground, and the king employed these moments in endeavouring to soften his conductor, and induce him to favour or permit his escape. His majesty represented the atrocity of the crime he had committed in attempting to murder his sovereign, and the invalidity of an oath taken to perpetrate so heinous an action. Kosinski lent attention to this discourse, and began to betray some symptoms of remorse. The king pursued the advantage he had gained, overcame the fears of Kosinski, and was at length reconducted to the capital. Upon his return to Warsaw he was received with the utmost demonstrations of joy. But neither the virtues nor the popularity of the sovereign could allay the factious spirit of the Poles, nor prevent the dismemberment of his kingdom.

First partition of Poland.

The partition of Poland was first projected by the king of Prussia. Polish or Western Prussia had long been an object of his ambition. Exclusively of its fertility, commerce, and population, its local situation rendered it highly valuable to that monarch; it lay between his German dominions and Eastern Prussia, and, whilst in the possession of the Poles, it cut off at their will all communication between them. The period had now arrived when the situation of Poland seemed to promise the easy acquisition of this valuable province. Frederic, however, pursued it with all the caution of an able politician. On the commencement of the troubles, he showed no eagerness to interfere in the affairs of this country; and although he had concurred with the empress of Russia in raising Stanislas Augustus to the throne of Poland, yet he declined taking any active part in his favour against the confederates. Afterwards, when, in 1769, the whole kingdom became convulsed with civil commotions, and desolated by the plague, he, under pretence of forming lines to prevent the spreading of the infection, advanced his troops into Polish Prussia, and occupied the whole of that district. Though now completely master of the country, and by no means apprehensive of any formidable resistance from the disunited and distracted Poles, yet, as he was well aware that the security of his new acquisition depended upon the acquiescence of Russia and Austria, he planned the partition of Poland. He communicated the project to the emperor, either upon their interview at Niess in Silesia in 1769, or in that of the following year at Nieustadt in Austria, and from him the overture met with a ready concurrence. To induce the empress of Russia to acquiesce in the same project, he despatched to St Petersburg his brother Henry, who suggested to the empress, that the house of Austria was forming an alliance with the Porte, with which she was then at war; that if such alliance took place, it would create a most formidable combination against her; that, nevertheless, the friendship of that house was to be purchased by acceding to the partition; that, upon this condition, the emperor was willing to renounce his connection with the grand signior, and would suffer the Russians to prosecute the war without interruption. Catharine, anxious to push her conquests against the Turks, and dreading the interposition of the emperor in that quarter; perceiving, likewise, from the intimate union between the courts of Vienna and Berlin, that it would not be in her power, at the present juncture, to prevent the intended partition; closed with the proposal, and selected no inconsiderable portion of the Polish territories for herself. The treaty was signed at St Petersburg in the beginning of February 1772, by the Russian, Austrian, and Prussian plenipotentiaries. It would be tedious to enter into a detail of the pleas urged by the three powers in favour of their several demands; nor would it be less uninteresting to lay before the reader the answers and remonstrances of the king and senate, as well as the appeals to the other states which had guaranteed the possessions of Poland. The courts of London, Paris, Stockholm, and Copenhagen, remonstrated against these usurpations; but remonstrances without assistance could be of no effect. Poland submitted to the dismemberment, not without the most violent struggles; and now for the first time that unhappy country felt and lamented the fatal effects of faction and discord.

A Diet being demanded by the partitioning powers, in order to ratify the cession of the provinces, it met on the 19th of April 1773; and such was the spirit of the members, that, notwithstanding the deplorable situation of their country, and the threats and bribes of the three powers, the partition-treaty was not carried through without much difficulty. For some time the majority of the nuncios appeared determined to oppose the dismemberment, and the king firmly persisted in the same resolution. The ambassadors of the three courts enforced their requisitions by the most alarming menaces, and threatened the king with deposition and imprisonment. They also gave out by their emissaries, that in case the Diet continued refractory, Warsaw should be pillaged. This report was industriously circulated, and made a sensible impression upon the inhabitants. By menaces of the same sort, by corrupting the marshal of the Diet, and by bribes, promises, and threats, the members were at length prevailed on to ratify the dismemberment.

The partitioning powers, however, did less injury to the republic by dismembering its fairest provinces, than perpetuating the principles of anarchy and confusion. Under pretence of amending the constitution, they confirmed all its defects, and took effectual precautions to render this unhappy country incapable of ever emerging from the deplorable state into which it had fallen; as was seen in the failure of the most patriotic attempt ever made by a king to reform the constitution of his kingdom.

The kings of Poland originally hereditary, but afterwards elective.

The kings of Poland were anciently hereditary and absolute, but afterwards became elective and limited. In the reign of Louis, towards the end of the fourteenth century, several limitations were imposed on the royal prerogative. In that of Casimir IV. who ascended the throne in 1446, representatives from the several palatinates were first called to the Diet; the legislative power till then having been lodged in the states, and the executive in the king and senate. On the decease of Sigismund Augustus, it was enacted by law, that for the future the choice of a king should perpetually remain free and open to all the nobles of the kingdom; and this law was accordingly observed, to the great injury of the kingdom.

As soon as the throne became vacant, all the courts of justice, and other parts of the machine of government, remained in a state of inaction, and the authority was transferred to the primate, who, in quality of interrex, had in some respects more power than the king himself; and yet the republic took no umbrage at this, because he had not time to render himself formidable. He notified the vacancy of the throne to foreign princes, which was in effect proclaiming that a crown was to be disposed of; he issued the *universalia*, or circular letters for the election; he gave orders to the starosts, a sort of military officers who had great authority, and whose proper business it was to levy the revenue, to keep a strict guard upon the fortified places, and enjoined the grand generals to do the same upon the frontiers, towards which the army marched.

The place of election was the field of Vola, at the gates of Warsaw; and all the nobles of the kingdom had a right of voting. The Poles encamped on the left side of the Vistula, and the Lithuanians on the right, each under the banners of their respective palatinates. The field of election was surrounded by a ditch provided with three gates; one to the east for Great Poland, another to the south for Little Poland, and a third to the west for Lithuania. In the middle of the field was erected a great building of wood, named the *szopa*, or hall of the senate. All who aspired openly to the crown were expressly excluded from the field of election, that their presence might not constrain the voters. The king must be elected *nemine contradicente*, by all the suffrages without exception. The law which prescribed unanimity was founded upon this principle, that when a great family adopts a father, all the children have a right to be pleased. The idea seems plausible in speculation; but if it were rigorously adhered to, Poland could never have had such thing as a lawful king. They therefore gave up a real unanimity, and contented themselves with the appearance or semblance of concord.

No election could possibly be carried on with more order, decency, and appearance of freedom. The primate in few words recapitulated to the nobles on horseback the respective merits of the candidates; he exhorted them to choose the most worthy, invoked heaven, gave his blessing to the assembly, and remained alone with the marshal of the Diet, whilst the senators dispersed themselves into the several palatinates to promote an unanimity of sentiment. If they succeeded, the primate himself went to collect the votes, at the same time naming again all the candidates. "Szoda," answered the nobles, "that is the man we choose;" and instantly the air resounded with his name, together with cries of *vivat*, and the noise of pistols. If all the palatines agreed in their nominations, the primate got on horseback, and then, the profoundest silence succeeding to the greatest noise, he asked three times if all were satisfied, and, after a general approbation, three times proclaimed the king; upon which the grand marshal of the crown repeated the proclamation three times at the three gates of the camp.

The pacta conventa.

Before the king was proclaimed, the *pacta conventa* were read aloud to him, which, on his knees at the altar, he swore to observe. This contract, which had been drawn up, methodized, and approved by the senate and nobility, was deemed the great charter of Poland. It provided that the king should not attempt to encroach on the liberty of the people, by rendering the crown hereditary in his family; that he should preserve all the customs, laws, and ordinances respecting the freedom of election; that he should ratify all treaties subsisting with foreign powers, which were approved by the Diet; that it should be his chief study to cultivate peace, preserve the public tranquillity, and promote the interest of the realm; that he should not coin money except in the name of the republic, or appropriate to himself the advantages arising from coinage; that in declaring war, concluding peace, making levies, hiring auxiliaries, or admitting foreign troops upon any pretext within the Polish dominions, the consent of the Diet and senate should be necessary; that all offices and preferments should be given to the natives of Poland and Lithuania, and that no pretence should excuse or palliate the crime of introducing foreigners into the king's council or the departments of the republic; that the officers of his majesty's guards should be Poles or Lithuanians, and that the colonel should absolutely be a native of Poland, and of the order of nobility;

that all the officers should be subordinate to the authority of the marshal; that no individual should be invested with more employments than the law allows; that the king should not marry without the approbation of the senate; that the sovereign should never apply his private signet to acts and papers of a public nature; that the king should dispose of the offices both of the court and of the republic, and regulate with the senate the number of forces necessary for the defence of the kingdom; that he should administer justice by the advice of the senate and his council; that the expenses of his civil list should be the same with those of his predecessors; that he should fill up all vacancies in the space of six weeks; that this should be his first business in the Diet, obliging the chancellor to publish his appointments in due form; that the king should not diminish the treasure kept at Cracow, but, on the contrary, endeavour to augment it, as well as the number of the crown jewels; that he should not borrow money without the consent of the Diet; that he should not equip a naval force, without the consent and full approbation of the republic; that he should profess the Roman Catholic faith, and promote, maintain, and defend it, throughout all the Polish dominions; and, finally, that all their several liberties, rights, and privileges, should be preserved to the Poles and Lithuanians in general, and to all the districts and provinces contained within each of these great divisions, without change, alteration, or the smallest violation, except by the consent of the republic. To these articles a variety of others were added, according to circumstances and the humour of the Diet; but what has been recited formed the standing conditions, which were scarcely ever altered or omitted.

Th iet of Pol d.

The Diet of Poland was composed of the king, the senate, bishops, and the deputies of the nobility or gentry of every palatinate, called, in their collective capacity, *comitia togata*, that is, when the states assembled in the city without arms and horses; or *comitia paludata*, when they met in the fields armed, as during an interregnum, at the Diet of election. It was a prerogative of the crown to assemble the Diet at any particular place, except on occasion of a coronation, which the custom of the country required should be celebrated at the capital. For a number of years, indeed, the Diet assembled regularly at Warsaw; but, on complaints being made by the Lithuanians, it was agreed that every third Diet should be held at Grodno. When it was proposed to hold a general Diet, the king, or, in case of an interregnum, the primate, issued writs to the palatines of the several provinces, specifying the time and place of the meeting. A sketch likewise was sent of the business to be deliberated on by the assembly; the senate was consulted in this particular, and six weeks were allowed the members to prepare themselves for the intended session. It is remarkable, that the Diet never sat more than six weeks in the most critical conjunctures and pressing emergencies; nay, they have been known to break up in the middle of an important debate, and to leave the business to a future meeting. This custom has been justly esteemed one of the greatest defects of the Polish constitution; but it probably owed its origin to convenience, and was afterwards superstitiously observed from whim and caprice. On receipt of the king's writ, the palatine communicated the meeting of the Diet to all the castellans, starosts, and other inferior officers and gentry within his jurisdiction; requiring them to assemble on a certain day to elect deputies, and take into consideration the business specified in the royal summons. These meetings were called petty diets, *dietines*, or *lantage*, in the language of the country, every gentleman possessing three acres of land having a vote, and matters being determined by a majority; whereas in the general Diet decrees were only valid when the whole body was unanimous. Every palatinate had three representatives, though the business devolved on one called a nuncio, who was elected on account of his ability and experience; and the other two were added only to give weight to this leading member, and by their magnificent appearance do honour to the palatinate which they represented. As these deputies, since the reign of Casimir III. had seats in the Diet, it naturally divided the general assembly into two bodies, the upper and lower; the one being composed of the senate, the superior clergy, and the great officers; and the other of the representatives of the palatinates, who prepared all business for the superior body.

Absurd customs observed in the Diet.

The first business of the assembly was to choose a marshal, upon which occasion the debates and tumults often ran high. After his election the marshal kissed the king's hand; and the chancellor, as the royal representative, reported the matter to be deliberated by the Diet. Then the marshal acquainted the king with the instructions the deputies had received from their constituents, the grievances which they would have redressed, and the abuses they required to be remedied. He likewise requested his majesty to fill up the vacant offices and benefices according to law; and he was answered by a formal speech from the chancellor, who reported the king's inclination to satisfy his people, as soon as he had consulted his faithful senate. In certain customs observed by the Polish Diet, there was something peculiarly absurd and preposterous. One in particular merits attention. Not only was an unanimity of voices necessary to pass any bill, and constitute a decree of the Diet, but every bill likewise required to be unanimously assented to, or none could take effect. Thus, if out of twenty bills one happened to be opposed by a single voice, called the *liberum veto*, all the rest were thrown out, and the Diet had met, deliberated, and debated, during six weeks, to no purpose whatever.

Its venality and corruption.

To add to the inconveniences which attended the constitution of the Diet of Poland, a spirit of venality in the deputies, and a general corruption, had seized all ranks and degrees in that assembly. There, as in some other countries, the cry of liberty was kept up for the sake of private interest. Deputies came with a full resolution of profiting by their patriotism, and not lowering their voice without a gratification. Determined to oppose the most salutary measures of the court, they either withdrew from the assembly, and protested against all that should be transacted in their absence, or else excited such a clamour as rendered it necessary for the court to silence them by some lucrative pension, donation, or employment. Thus the business of the assembly was not only obstructed by its own members, but frequently by largesses from neighbouring powers, and sometimes by the liberality of an open enemy, who had the art of distributing his money with discretion.

The Senate of Poland.

Perhaps the most respectable department of the Polish government was the senate, composed of the bishops, palatines, castellans, and ten officers of state, who derived a right from their dignities of sitting in that assembly, and amounting in all to a hundred and forty-four members, who were styled "senators of the kingdom," or "counsellors of the state," and had the title of excellency, a dignity supported by no pension or emoluments necessarily annexed to it. The senate presided over the execution of the laws, and was the guardian of liberty, the judge of right, and the protector of justice and equity. All the members, except the bishops, who were senators *ex officio*, were nominated by the king, and took an oath to the republic before they were permitted to enter upon their functions. Their honours continued for life. At the general Diet they sat on the right and left of the sovereign, according to their dignity, without regard to seniority. They were the mediators between the monarch and the subject, and, in conjunction with the king, ratified all the laws passed by the nobility. As a senator was bound by oath to maintain the liberties of the republic, it was thought no disrespect to majesty that they reminded the prince of his duty. They were his counsellors, and this freedom of speech constituted an inseparable prerogative of their office.

The Permanent Council.

Such was the constitution of Poland before being new-modelled by the partitioning powers. That it was in all respects a very bad one, needs no proof whatever But those foreign reformers did not improve it. For two centuries at least, the Poles had with great propriety denominated their government a republic, because the king was so exceedingly limited in his prerogative that he resembled more the chief of a commonwealth than the sovereign of a powerful monarchy. That prerogative, already too confined to afford protection to the peasants, groaning under the tyranny of the nobles, was, after the partition-treaty, still further restrained by the establishment of the Permanent Council, which was vested with the whole executive authority, leaving to the sovereign nothing but the name. The permanent council consisted of thirty-six persons, elected by the Diet out of the different orders of nobility; and though the king, when present, presided in it, he could not exert a single act of power without the consent of the majority of persons, who might well be called his colleagues.

That the virtuous and accomplished Stanislas should have laboured to extricate himself and the great body of the people from such unparalleled oppression, and that the more respectable portion of the nation should have wished to give to themselves and their posterity a better form of government, was surely very natural and very meritorious. The influence of the partitioning powers was indeed exerted to render the king contented with his situation. His revenues, which before did not exceed L.100,000, were now increased to three times that sum. The republic likewise agreed to pay his debts, amounting to upwards of L.400,000. It also bestowed on him, in hereditary possession, four starosties or governments of castles, with the districts belonging to them, and reimbursed him for the money which he had laid out on account of the state. It was likewise agreed that the revenues of the republic should be raised to thirty-three millions of florins, or nearly two millions sterling; and that the army should consist of thirty thousand men. Soon after the conclusion of peace with Turkey, the empress of Russia also made the king a present of 250,000 rubles, as a compensation for that part of his dominions which had fallen into her hands.

A new constitution established in 1791.

These bribes, however, were not sufficient to blind the penetration of Stanislas, nor to cool the ardour of his patriotism. He laboured for posterity, and with such apparent success, that on the 3d of May 1791, a new constitution of the government of Poland was established by the king, together with the confederate states assembled in double number to represent the Polish nation. That this constitution was perfect, we are far from asserting; but it was probably as much so as the inveterate prejudices of the nobles would admit of. It deviated as little as possible from the ancient forms, and consisted of eleven articles respecting the government of the republic, to which were added twenty-one sections, regulating the dietines or primary assemblies of Poland.

Substance of the first five articles.

The first article of this constitution established the Roman Catholic faith, with its various privileges and immunities, as the dominant national religion; but to all other people, of whatever persuasion, it secured peace in matters of faith, and the protection of government. The second article guaranteed to the nobility or the equestrian order all the privileges which it enjoyed under the kings of the house of Jagellon. The third and fourth articles granted to the free royal towns internal jurisdictions of their own; and exempted the peasants from slavery, declaring every man free as soon as he set his foot on the territory of the republic. The fifth article, after declaring, that in civil society all power should be derived from the will of the people, enacted that the government of the Polish nation should be composed of three distinct powers; the Legislative, in the states assembled; the Executive, in the king and the council of inspection; and the Judicial power, in the jurisdictions existing or to be established. The sixth and seventh articles, as being of more importance, we shall state the substance of at greater length.

The L to con two ho

According to the former, the Diet, or the legislative power, was to be divided into two houses, viz. the House of Nuncios or deputies, and the House of Senate, where the king was to preside. The former, being the representative and central point of supreme national authority, was to possess the pre-eminence in the legislature; therefore all bills were to be decided first in this house.

House Nunc

Within the competency of the House of Nuncios were included all general laws, constitutional, civil, and criminal, besides perpetual taxes; matters concerning which the king was to issue his propositions by the circular letters sent before the dietines to every palatinate and to every district for deliberation, and which, coming before the house with the opinions expressed in the instructions given to their representatives, should be taken the first for decision. Next, particular laws, viz. temporal taxes; regulations of the mint; contracting public debts; creating nobles, and other casual recompenses; reparation of public expenses, both ordinary and extraordinary; concerning war and peace, with the ratification of treaties both political and commercial; all diplomatic acts and conventions relative to the laws of nations; examining and acquitting different executive departments, and similar subjects arising from the accidental exigencies and circumstances of the state; in all which the propositions coming directly from the throne into the house of nuncios, were to have a preference in discussion before the private bills.

The H of Sen

In regard to the House of Senate, it was to consist of bishops, palatines, castellans, and ministers, under the presidency of the king, who should have but one vote, and the casting voice in case of parity, which he might give either personally or by a message to the house. Its power and duty were clearly defined. First, every general law that passed formally through the house of nuncios was to be sent immediately to this, which either accepted or suspended it till further national deliberation, by a majority of votes, as prescribed by law. If accepted, it became a law in all its force; if suspended, it might be resumed at the next Diet, and if it was then agreed to again by the house of nuncios, the senate must submit to it. Secondly, in every particular law or statute of the Diet touching the matters above specified, as soon as it had been determined by the house of nuncios, and sent up to the senate, the votes of both houses should be jointly computed, and the majority, as described by law, should be considered as the will of the nation. Those senators and ministers who, from their share in the executive power, were accountable to the republic, had no active voice in the Diet, but might be present in order to give necessary explanations to the states.

The *lil rum ve* abolish

These ordinary legislative Diets were to have an uninterrupted existence, and be always ready to meet. The length of sessions was to be determined by the law concerning Diets. If convened upon some urgent occasion out of ordinary session, they were only to deliberate on the subject which occasioned such a call, or on circumstances which might arise out of it. No law or statute enacted by such ordinary Diet could be altered or annulled by the same. The majority of votes was to decide everything and everywhere; therefore the *liberum veto* was utterly abolished, together with all sorts of confederacies and confederate Diets, as contrary to the spirit of the constitution, as undermining the government, and as being ruinous to society. The framers of this constitution, willing to prevent violent and frequent changes in the national constitution, yet considering the necessity of perfecting it after experiencing its effects on public prosperity, determined the period of every twenty-five years for an extraordinary constitutional Diet, to be held for the revision of the constitution, and making such changes and alterations as might be found requisite.

ers of king council spec-

The seventh article proceeds on the principle that the most perfect government cannot exist or endure without an effectual executive power. The happiness of the nation depends on just laws, but the good effects of laws flow only from their execution. The framers of this constitution, therefore, having secured to the Polish nation the right of enacting laws for themselves, the supreme inspection over the executive power, and the choice of their magistrates, intrusted to the king and his council the highest power of executing the laws. This council was to be called *Straz*, or the Council of Inspection. The duty of such executive power was to watch over the laws, and to see them strictly executed according to their import, even by means of public force, should it be found necessary. All departments and magistrates were bound to obey its directions. This executive power could not assume the right of making laws, or of interpreting them. It was expressly forbidden to contract public debts; to alter the repartition of the national income, as fixed by the Diet; to declare war; to conclude definitively any treaty, or any diplomatic act; it was only allowed to carry on negotiations with foreign courts, and facilitate temporary occurrences, always with reference to the Diet.

crown.

The crown of Poland was declared to be elective in regard to families, and it was so settled for ever. But it was resolved to adopt hereditary succession to the throne. Therefore it was enacted and declared that, after the expiration of the present king's life, the elector of Saxony should reign over Poland, and in his person should the dynasty of future kings of Poland commence.

nation

Every king, on his accession to the throne, was to take a solemn oath to God and the nation, to support the present constitution, and to fulfil the *pacta conventa*. The king's person was sacred and inviolable. As no act could proceed immediately from him, he could not in any manner be responsible to the nation; he was not an absolute monarch, but the father and the head of the people; and his revenues, as fixed by the *pacta conventa*, were to be sacredly preserved. All public acts, the acts of magistracies, and the coin of the kingdom, were to bear his name. He had the right of pardoning those who were condemned to death, except the crimes were against the state; and in time of war he had the supreme command of the national forces, but he might appoint the commanders of the army, with the consent of the states. The nomination to all offices and dignities was vested in him.

Coun- In- ion.

The king's Council of Inspection was to consist of the primate as the head of the clergy, and the president of the commission of education, or the first bishop *in ordine;* of five ministers, viz. those of police, justice, war, finances, and foreign affairs; of two secretaries to keep the protocols, one for the council, and another for the foreign department; but both without a decisive vote. The hereditary prince, on coming of age, and having taken the oath to preserve the constitution, might assist at all sessions of the council, but could have no vote therein. The marshal of the Diet had also a right to sit in this council, without taking any share in its resolves, in order that he might call together the Diet, always existing; for, should he deem the convocation of the Diet absolutely necessary, and should the king refuse to do it, the marshal was bound to issue his circular letters to all nuncios and senators, adducing real motives for such meeting. The cases demanding such convocation of the Diet were the following: First, in a pressing necessity concerning the law of nations, and particularly in case of a neighbouring war; secondly, in case of an internal commotion, menacing the country with revolution, or of a collision between magistrates; thirdly, in an evident danger of general famine; fourthly, in the orphan state of the country, by demise of the king, or in case of the king's dangerous illness. All the resolutions of the council of inspection were to be examined by the rules above mentioned.

If it should happen that two thirds of secret votes in both houses demanded the changing of any person, either in the council, or any executive department, the king was bound to nominate another; and when these ministers were denounced and accused before the Diet, of any transgression of positive law, they were answerable with their persons and fortunes. Such impeachments being determined by a simple majority of votes, collected jointly from both houses, were to be tried immediately by the comitial tribunal, where the accused were to receive their final judgment and punishment if found guilty, or to be honourably acquitted on sufficient proof of innocence.

Commissions of education, &c.

In order to form a necessary organization of the executive power, there were established separate commissions, connected with the above council, and subject to its ordinations. These were commissions of education, of police, of war, and of treasury.

Administration of justice.

The eighth article regulated the administration of justice. It constituted primary courts of justice for each palatinate or district, composed of judges chosen at the dietine; and appointed higher tribunals, one being erected in each of the three provinces into which the kingdom was divided, with which appeals might be lodged from the primary courts. It likewise appointed for the trial of persons accused of crimes against the state, one supreme general tribunal for all classes, called a *comitial tribunal*, or court composed of persons chosen at the opening of every Diet. The ninth article provided a regency during the king's minority, in case of his settled alienation of reason, or upon the emergency of his being made a prisoner of war.

The election and duties of nuncios.

The regulation of the dietines contained nothing that can be interesting to a British reader, except what related to the election and duties of nuncios or representatives to the general Diet. And here it was enacted, that persons having a right to vote must all be nobles of the equestrian order; that is, all hereditary proprietors of landed property, or possessed of estates by adjudication for a debt, paying territorial tax to government; brothers inheriting estates before they have shared their succession; all mortgagees who paid a hundred florins of territorial tax per year from their possessions; and all life-holders of lands paying territorial tax to the same amount. All nobles in the army possessed of such qualifying estates had a vote in their respective districts in time of peace, and when absent on leave during war; and legal possession was understood to qualify when it had been acquired and actually enjoyed for twelve calendar months previously. Persons who had no right to vote were those of the equestrian order that were not actually possessed of a property as described in the foregoing article; such as held royal, ecclesiastical, or noble lands, even with right of inheritance, but on condition of some duty or payment to their principals; gentry possessing estates on feudal tenure, called *ordynackie*, as being bound to certain personal service thereby; all renters of estates that had no other qualifying property; those that had not attained eighteen years of age; persons *crimine notati*, and those that were under a decree passed in default, even in the first instance, for having disobeyed any judicial court.

Persons eligible and not eligible.

Every person of the equestrian order that paid territorial tax to government for his freehold, let it be ever so small, was eligible to all elective offices in his respective district. Gentlemen actually serving in the army, even possessed of landed hereditary estate, must have served six complete years before they could be eligible to the office of nuncio only. But this condition was dispensed with in favour of

History.

those that had before filled some public function. Whoever was not personally present at the dietine; whoever had not completed twenty-three years of age; whoever had not been in any public function, nor passed the biennial office of a commissary in the orderly commission; those that were not exempted by law from obligations of *scarta bellatus*, which subjected all newly-nobilitated persons to certain civil restrictions until the next generation; and, lastly, all those against whom might be objected a decree *in contumaciam* in a civil cause, were not eligible.

This constitution opposed by the Russians.

Such were the heads of the Polish constitution established by the king and the confederates in 1791. It will not bear a comparison with systems which have been matured by long experience; but it is surely infinitely superior to the motley form of government which, for a century previous, rendered Poland a perpetual scene of war, tumult, tyranny, and rebellion. Many of the corrupt nobles, however, perceiving that it would curb their ambition, deprive them of the base means which they had long enjoyed of gratifying their avarice by setting the crown to sale, and render it impossible for them to continue with impunity their tyrannical oppression of the peasants, protested against it, and withdrew from the confederates. This was nothing more than what might have been expected, or than what the king and his friends undoubtedly expected. But the malcontents were not satisfied with a simple protest; they preferred their complaints to the empress of Russia, who, ever ready on all occasions, and on the slightest pretence, to invade Poland, poured her armies into the republic, and surrounding the king and the Diet with ferocious soldiers, compelled them, by the most indecent menaces, to undo their glorious labour of love, and to restore the constitution as settled after the partition-treaty.

General rising.

On the 21st of April 1792, the Diet received the first notification from the king, of the inimical and unjust intentions of Russia. He informed them that, without the shadow of pretence, this power had determined to invade the territory of the republic with an army of sixty thousand men. This formidable force, commanded by Generals Soltikof, Michelson, and Kosakowski, was afterwards to be supported by a corps of twenty thousand, and by the troops then acting in Moldavia, amounting to seventy thousand. The king, however, professed that he was not discouraged; and he declared his readiness to put himself at the head of the national troops, and to terminate his existence in a glorious contest for the liberties of his country. Then, and not before, the Diet decreed the organization of the army, and its augmentation to a hundred thousand. The king and the council of inspection were invested with unlimited authority in everything that regarded the defence of the kingdom. Magazines were ordered to be constructed when it was too late, and quarters to be provided for the army. The Diet and the nation rose as one man to maintain their independence. All private animosities were obliterated, all private interests were sacrificed; the greatest encouragements were held forth to volunteers to enroll themselves under the national standard; and it was unanimously decreed by the Diet that all private losses should be compensated out of the public treasury.

Russian declaration.

On the 18th of May the Russian ambassador delivered a declaration worthy of such a cause. It asserted that this wanton invasion, which was evidently against the sense of almost every individual Pole, was intended solely for the good of the republic. It censured the precipitancy with which the new constitution had been adopted, and ascribed the ready consent of the Diet to the influence of the mob of Warsaw. It represented the constitution as a violation of the principles on which the Polish republic was founded; complained of the licentiousness with which the sacred name of the empress was treated in some speeches of the members; and concluded by professing, that on these accounts, and in behalf of the emigrant Poles, her imperial majesty had ordered her troops to enter the territories of the republic. At the moment when this declaration was delivered to the Diet, the Russian troops, accompanied by Counts Potocki, Rzewuski, Branicki, and a few Polish renegades, appeared upon the frontiers, and, before the close of the month, entered the territories of the republic in several columns.

Spirit
the no

The spirit manifested by the nobility was truly honourable to that body. Some of them delivered in their plate to the mint. Prince Radzivil engaged voluntarily to furnish ten thousand stand of arms, and another noble offered to provide a train of artillery. The courage of the new and hastily embodied soldiers corresponded with the patriotism of their chiefs. Prince Poniatowski, nephew of the king, was appointed commander-in-chief; and though his force was greatly inferior to the enemy, it must be confessed that he made a noble stand.

Conduc
the cou
of Berli

The perfidy, the meanness, and the duplicity manifested by Prussia on this occasion is probably without a parallel in history. By the treaty of defensive alliance, solemnly contracted between the republic of Poland and the king of Prussia, and ratified on the 23d of April 1790, it is expressly stipulated, that the contracting parties shall do all in their power to guarantee and preserve to each other reciprocally the whole of the territories which they respectively possess; that, in case of menace or invasion from any foreign power, they shall assist each other with their whole force, if necessary; and that if any foreign power whatever should presume to interfere in the internal affairs of Poland, his Prussian majesty would consider this as a case falling within the meaning of the alliance, and assist the republic according to the tenor of the above article, that is, with his whole force. What, then, was the pretext for violating this treaty? It was this, that the empress of Russia had shown a decided opposition to the order of things established in Poland on the third of May 1791, and was provoked by Poland presuming to put herself into a posture of defence. It is ascertained, however, by the most authentic documents, that nothing was effected on the 3d of May 1791, to which Prussia had not previously assented, and which she did not afterwards sanction; and that Prussia, according to the assertion of her own king, did not intimate a single doubt respecting the revolution till several months after it had taken place; in short, to use the king's own words as explanatory of his double politics, "not till the general tranquillity of Europe permitted him to explain himself." Instead, therefore, of assisting Poland, Prussia insultingly recommended to Poland to retrace her steps; in which case, she said that she would be ready to attempt an accommodation in her favour. But this attempt was never made, and probably never intended; for the empress pursued her measures without opposition.

War wi
Russia.

The duchy of Lithuania was the great scene of action in the beginning of the war. But the Russians had made little progress before the middle of the month of June. On the 10th of that month, General Judycki, who commanded a detachment of the Polish troops between Mire and Swierzna, was attacked by the Russians; but, after a combat of some hours, he obliged them to retire with the loss of five hundred men dead on the field. The general was desirous of profiting by this advantage, by pursuing the enemy, but was prevented by a violent fall of rain. On the succeeding day, the Russians rallied again to the attack; and it then too fatally appeared that the Poles, being young and undisciplined, were unable to contend with an inferior force against experienced troops and able generals. By a masterly manœuvre, the Russians contrived to surround their antagonists, at a moment when the Polish general supposed that he had obliged the enemy to retreat; and though the field was contested with the utmost valour by the troops of the republic, they were at length compelled to give way, and to retire towards Nieswiesz.

On the 14th another engagement took place near Lubar, on the banks of the river Sluez, between a detachment of the Russian grand army and a party of Polish cavalry despatched by Prince Joseph Poniatowski to intercept the enemy. The patriotic bravery of the Poles proved victorious in this contest; but upon reconnoitring the force of the enemy, the prince found himself incapable of making a successful stand against such superior numbers. He, therefore, gave orders to strike the camp at Lubar, and commenced a precipitate retreat. During their march, the Polish rear was harassed by a body of about four thousand Russians. The Polish army next directed its course towards Zielime, where meeting, on the 17th, with a reinforcement from Zaslow, it halted to give battle to the enemy. The Russians were upwards of seventeen thousand strong, with twenty-four pieces of cannon, and the force of the republic much inferior. After a furious contest, from seven in the morning till five in the afternoon, the Russians were at length obliged to retreat, and leave the field of battle in possession of the patriots.

Notwithstanding these exertions, the Poles were obliged gradually to retire before their numerous and disciplined enemies. Nieswiesz, Wilna, Minsk, and several other places of less consequence, fell one after another into their hands. On a truce being proposed to the Russian general Kochowski, the proposal was haughtily rejected; whilst the desertion of vice-brigadier Rudnicki and some others, who preferred dishonour to personal danger, proclaimed a tottering cause. The progress of the armies of Catharine was marked with devastation and cruelty; whilst such was the aversion of the people, both to the cause and the manner of conducting it, that, as they approached, the country all around became a wilderness, where scarcely a human being was to be seen.

In the mean time, a series of petty defeats, to which the inexperience of the commanders, and the intemperate valour of newly-raised troops, appear to have greatly contributed, served at once to distress and dispirit the defenders of their country. Prince Poniatowski continued to retreat; and on the 17th of July, his rear being attacked by a very superior force, it suffered a considerable loss, although the skill and the courage of General Kosciuszko enabled him to make a most respectable defence. On the 18th, a general engagement took place between the two armies. The Russian line extended opposite Dubienka, along the river Bug, as far as Opalin; and the principal column, consisting of fourteen thousand men, was chiefly directed against the division of General Kosciuszko, which consisted only of five thousand men. After a most vigorous resistance, in which the Russians lost upwards of four thousand men, the troops of the republic were compelled to give way before the superior numbers of the enemy, and to retire further into the country.

The king proposes submission.

This unequal contest was at last prematurely terminated. The king, whose benevolent intentions were, perhaps, overpowered by his mental imbecility, and whose age and infirmities, probably, rendered him unequal to the difficulties and dangers which must attend a protracted war, instead of putting himself at the head of his army, determined at once to surrender at discretion. On the 23d of July he summoned a council of all the deputies at that moment in Warsaw, and laid before them the last despatches from the empress, which insisted upon total and unreserved submission. He pointed out the danger of a dismemberment of the republic, should they delay to throw themselves upon the clemency of the empress, and to entreat her protection. He also mentioned the fatal union of Austria and Prussia with Russia, and the disgraceful supineness manifested by every other court in Europe. Four citizens, the intrepid Malachowski, and the Princes Sapieha, Radzivil, and Soltan, vehemently protested against these dastardly proceedings; and the following evening a company of gentlemen from the different provinces attended for the same purpose. The assembly immediately waited upon these four distinguished patriots, and returned them their acknowledgements for the spirit and firmness with which they had resisted the usurpations of despotism. The submission of the king to the designs of Russia was no sooner made known than Poland was bereft of all her best and most respectable citizens. Malachowski, as marshal of the Diet, and Prince Sapieha, grand marshal of Lithuania, entered on the journals of the Diet strong protests against these proceedings, and declared solemnly that the Diet legally assembled in 1788 was not dissolved.

The former constitution restored.

On the second of August a confederation was formed at Warsaw, of which the renegade Potocki was chosen marshal. The acts of this confederation were evidently the despotic dictates of Russia, and were solely calculated to restore the ancient abuses, and to place the country under the aggravated oppression of a foreign yoke. It is remarkable, however, that at the very moment when Poland was surrendering its liberties to its despotic invaders, the generous sympathy of Great Britain was evinced by a liberal subscription, supported by the most respectable characters in the nation, of every party and of every sect, for the purpose of assisting the king and the republic to maintain their independence; and though the benevolent design was frustrated, yet the fact remains on record as a noble testimony of the spirit by which Britons are animated in the cause of freedom, of the indignation which fills every heart in this empire at the commission of injustice, and of the liberality with which all are disposed to assist those who suffer from the oppression of tyrants.

Part of the Polish territory seized.

Not satisfied with restoring the old wretched constitution, the empress of Russia seized upon part of the territory which, at the last partition, she and her coadjutors had left to the republic; and her ambassador entering into the Diet with a crowd of armed men, compelled the king and that assembly to grant the form of legality to her usurpations. The nation, however, did not submit.

Gallant effort of Kosciuszko.

In February 1794 General Kosciuszko appeared in the neighbourhood of Cracow with a small force of armed peasants. He beat some detachments of Russians and Prussians, compelled them to evacuate Cracow, and there proclaimed the constitution of 1791. Everywhere the people and the nobles flew to arms. The Russians, who occupied Warsaw with fifteen thousand men, began to seize suspected persons, and demanded possession of the arsenal. But at that moment the news arrived of a defeat sustained by a corps of six thousand Russians, with the loss of a thousand killed, and their general, Woronzow, made prisoner. Encouraged by this event, the people rose on the garrison, and after forty-eight hours' hard fighting, drove them out, with the loss of six thousand killed, three thousand prisoners, and fifty pieces of cannon. The whole country was now in arms. Russia and Prussia, however, sent a hundred and ten thousand men into Poland. Kosciuszko, pressed by superior forces, made an able retreat upon Warsaw. The king of Prussia, after besieging the city during three months, was compelled to retire towards his own territories with the loss of twenty thousand men. Here he was harassed for some time by Madalinsky with a small corps of cavalry. Kosciuszko, relieved from the Prussians, marched against the new Russian armies, which, during the siege of Warsaw, had reconquered Lithuania and Volhynia. But the battle of Noezylac, on the 10th of October 1794, in which the Poles fought with heroic resolution against overpowering numbers, proved fatal to their unhappy country. Kosciuszko was made prisoner and carried to St Petersburg, where he languished in a dungeon until the death of Catharine. The

Russians, after this event, united their forces and marched upon Warsaw, where the Poles had named Wawrzecky general-in-chief. He had only ten thousand men to oppose to fifty thousand, but an obstinate resistance was nevertheless offered. The last remains of the national army were concentrated at Praga, on the right bank of the Vistula, immediately opposite Warsaw; but they were soon broken by the furious charges of the Russian general Suwarof, who gratified his natural cruelty by the most frightful carnage. The fate of Poland was now decided. After the capture of Praga, Warsaw capitulated. Nine thousand Poles fell in the fight; thirty thousand persons of all ages and either sex were destroyed in cold blood; and thirty thousand more, who still refused to submit, were suffered to leave the place, and afterwards hunted down by the soldiery. The most distinguished chiefs were carried away to distant provinces; and the wretched king was sent to Russia, where he ended his days in 1798.

Treaty of partition.

The two powers were proceeding to divide the remaining provinces between them, when Austria interfered, and declared that she would not permit the destruction of Poland unless she received a share. At that moment it was not thought prudent to raise up a new enemy; and Austria obtained a considerable addition of territory, without having struck a blow or expended a florin. The negotiation continued till 1795, when the definitive treaty of partition was signed, which closed a series of transactions unparalleled for perfidy, cruelty, and infamy in the history of Europe. Austria received Cracow, with the country lying between the Pilitsa, the Vistula, and the Bug. Prussia had the capital, with the territory as far as the Niemen. The lion's share, as usual, fell to Russia. After an existence of near ten centuries, the republic was thus erazed from the list of nations. No people on earth, perhaps, have ever shown so much personal bravery as the Poles. Their whole history indeed is full of wonderful victories. But with such a vicious frame of society as we have already described, the most chivalrous valour, and the most splendid military successes, could avail nothing. It could not enforce obedience to the laws, nor maintain domestic tranquillity; it could not preserve the proud nobles from dissipation, nor prevent them from receiving bribes to repair their shattered fortunes; it could not restrain the powers which lavished the means of corruption from interfering in the affairs of the kingdom; it could not dissolve the union of these powers with the malcontents at home; it could not infuse vigour into a government corrupted by foreign gold, nor avert the invasion of foreign armies to support the factious and rebellious; it could not, while divided against itself, uphold the independence of the nations against foreign and domestic treason; in a word, it could not effect impossibilities, and though it might dazzle by its glory, it could not counteract those slow but sure-working causes which determined the inevitable doom of Poland.

This great crime committed with impunity.

The extinction of the Polish republic afforded ample scope for political declamation. The tribunes of France, the parliament of England, and the press of both countries, resounded with eloquent invectives against the perfidy and violence of the partitioning powers, and general sympathy was awakened in favour of a people whose great actions were entitled to admiration, whilst their misfortunes moved our commiseration. But complete impunity awaited the despoilers of that unhappy country. The troubled state of affairs throughout Europe did not permit any power to interfere in behalf of the oppressed. A selfish and shortsighted policy paralysed every arm, and chilled every heart. The great cause of public justice and national independence found no advocates, whilst the attention of all was absorbed in a narrow and confined struggle for their own preservation. The three potentates were therefore enabled to perfect their common wickedness without the slightest hindrance; to repress the indignant efforts of the sufferers; to crowd their prisons with the best and bravest, who had either distinguished themselves in the recent struggle, or had ventured to express dissatisfaction with the new state of things; to disarm the inhabitants of the great towns, and to establish formidable garrisons of foreign troops, who were ready to crush the very first attempt at insurrection.

Compa the Po with F

The Poles had no longer a country to fight for or defend; they had lost everything but honour and the feeling of revenge. They carried all they had left, namely, their valour, into the market, and soon entered into a compact with republican France. At Cracow was formed a secret confederation, the members of which offered to the French Directory to sacrifice their lives at the first call of the republic. Nor was this a vain or futile offer. Hundreds of the warlike nobles, escaping from bondage at home, proceeded to Venice or to Paris, and under Dombrowski, their brave leader, were formed Polish legions, in aid of the newly-created Italian republics, and ready to act wherever their services might be required. Their pay and subsistence were to be furnished by the Italian states; they preserved their national arms and dress; and, taking as their motto that all freemen are brothers, they fully participated in that daring spirit which then shook Europe to its centre. That they were allured by the prospect which had been held out to them of their country's restoration, is well known; and if their faith was rather the measure of their own ardent hopes than the result of any rational or well-grounded conviction, it may at least be pleaded in their favour, that the unfortunate are naturally credulous, and that a true Pole can never eradicate from his heart the belief that all his fondest wishes will one day be gratified. But be this as it may, their martial prowess contributed essentially to the success of the republican cause. Their number was increased by fresh recruits, which more than compensated the casualties of the field; their brilliant valour shone resplendent in every battle where they were engaged; patriotism and revenge alike nerved their arms for the conflict. But they soon had occasion to distrust the fair professions of the republican hero. When anxious, by his means, to preserve an entrance to the congress of Rastadt for a representative of Poland, they were coolly told that the hearts of all friends of liberty were for the brave Poles, but that time and destiny alone could restore them as a nation. Still they did not despair. If the day of regeneration was deferred, might it not yet arrive, perhaps at no distant period, when a more favourable conjuncture of circumstances would render it impossible for the French government any longer to evade urging their claims? Where justice, and freedom, and independence were concerned, they could not believe that fortune would always frown on their cause, or that iniquity in high places would secure for itself an immunity from all retribution.

The nat of their connecti with Fra

The connection of the Polish legions with France exhibits the same unvaried picture of gallant services performed, and of hope deferred. Their loyalty was sustained by a strong passion for military fame; to them the tent was their home, the battle-field their country; and though they suffered severely, particularly during the absence of Napoleon in Egypt, yet they repaired their losses with astonishing promptitude, and, in the year 1801, amounted to fifteen thousand. But their blood flowed in vain. In every treaty which their valour had been instrumental in winning, their services were overlooked, and their country was forgotten. In Italy and on the Danube, Generals Dombrowski and Kniaziewiez, with their legions, represented the Polish nation, and maintained its ancient renown in arms, though to little purpose, as far as regarded their country. For five years, their bravery proved unavailing, in as far as concerned the main object for which they had fought and bled.

But with the year 1806 new hopes began to revive. The

C paigns of 06 an 1807.

brilliant campaign of that year, the simultaneous victories of Jena and Auerstadt, and the advance of the French army into Poland, seemed an earnest of future success, a sure pledge of approaching restoration. A general burst of enthusiasm followed. Polish regiments were organized with amazing rapidity, and the approach of Kosciuszko was proclaimed. On the 27th of November, Napoleon entered Posen in triumph; in December Warsaw received him with not less enthusiasm; a commission of government was immediately organized; and as his purpose was announced, his armies were recruited by thousands of the best troops in Europe. The battle of Eylau had been a mere butchery, unproductive of any result; but on the field at Friedland, Dombrowski had given signal proofs of his own talents and the valour of the heroes he commanded; and the opening of the negotiations at Tilsit was hailed by the Poles as the dawning of a bright and auspicious futurity. But the result proved that they had been far too sanguine in their anticipations. Napoleon in effect, though not probably in intention, betrayed them, and at the same time lost the opportunity of erecting a powerful barrier against the encroachments of Russia. Instead of restoring the kingdom of Poland in something like its ancient power and dimensions, he contented himself with forming a small portion of his conquests into the grand duchy of Warsaw, which he united with Saxony.

G d du y of W aw.

The duchy of Warsaw, thus established, consisted of the departments of Posen, Kalisch, Plock, Warsaw, Lomza, and Bydgoszez, with a population somewhat exceeding two millions. With this shred and mockery of a country the Poles were highly dissatisfied. They had been taught to expect that the ancient kingdom, if not Lithuania itself, would become irrevocably their own; and their mortification may therefore be conceived on finding that Prussia was to retain several palatinates, that Austria was guaranteed in her Polish possessions, that the provinces east of the Bug were to remain in the power of Russia, and that a considerable portion of the ancient republic west of that river, as far as the department of Bialystok, was ceded in perpetual sovereignty to the czar. Still the establishment of this duchy was probably intended as a point of departure in a new order of things, the ultimate term of which should be the restoration of Poland. By the new constitution, the Catholic religion was declared to be the religion of the state; but ample toleration, and even a community of civil rights, were allowed to the Dissidents. Serfage was abolished. In the king of Saxony, as grand duke of Warsaw, was vested the initiative of all bills or projects of law, the selection of senators, the nomination of the presidents of the dietines and the communal assemblies, and the appointment of all officers, civil and military; and the Code Napoleon was subsequently admitted as the basis of all judicial proceedings.

Re tions on s partial stora- tio

Something had thus been gained, though the arrangement was far from being satisfactory; indeed, by some the peace of Tilsit was regarded as the grave of all their hopes. But the greater number, reposing an unexhausted faith in the justice of their cause, consoled themselves with the belief that eventually Poland would be recalled into political existence, and her independence re-established upon a sure foundation. Accordingly, in the war with Austria in 1809, they rendered the most important services to Napoleon. They conquered Gallicia, without the smallest aid from France; they reduced Cracow and the adjoining territory; they regained possession of the capital, which the archduke had temporarily occupied; and they humbled their enemies on every side. What their own arms had won, they conceived that they had a right to retain, and they regarded as inevitable the incorporation of these conquests with their infant state. But they were destined to be speedily undeceived. Not a foot of ground were they allowed to retain in Gallicia; and half of their other conquests between the capital and the Austrian frontier was wrested from their hands. Four departments were indeed incorporated with the grand duchy, viz. Cracow, Pradom, Lublin, and Siedlec. This acquisition, however, afforded but a small compensation for the sacrifices which had been made, the forcible loans which had been raised, the lives which had been wasted, and the misery which afflicted every class of the inhabitants. In truth, the policy pursued by Napoleon in regard to the Poles bore traces of doubt and hesitation; it was always timid, seldom judicious, never generous. He had not the courage to break through the entanglements of diplomacy, by which his inclinations were fettered, and to do a great act of retributive justice, leaving the consequences to Providence. He suffered himself to be paralyzed by conflicting pretensions, and sacrificed his own glory to conciliate powers who took the earliest opportunity of betraying him.

Invasion of Russia in 1812.

Nevertheless, when the war with Russia became inevitable, Napoleon, with the view of interesting the Poles in his behalf, had recourse to all the arts of popular excitement, and, strange as it may seem, with his usual success. The more reflecting portion, wearied out and disgusted, refused to be again deluded. "We are flattered when our services are required," said they. "Is Poland always to be fed on hope alone?" The mass, however, swayed by their feelings, listened to the representations of the imperial agents, and a great body of Poles took the field, whilst a general confederation of nobles declared the republic restored, the declaration being signed by the king of Saxony, in whose house the hereditary monarchy was to be vested. But the enthusiasm thus excited proved short-lived. The reply of Napoleon to the Polish deputation, which had followed him to Wilna, at once dissolved the spell, by showing the deputies that he had guaranteed to the Emperor Francis the integrity of the Austrian possessions in Poland. Illyria therefore could not, as they had hoped, be exchanged for Gallicia; and as to Lithuania, Napoleon not only considered, but even proclaimed it a hostile country, and treated it accordingly. But still the deputation erred egregiously in giving up all for lost. Everything depended on the success of the expedition, which would have enabled Napoleon to give the law to Austria as well as to Russia; and hence, when he exhorted them to fight for their own independence, and assured them that if all the palatinates combined they might reasonably expect to attain their object, he gave them advice which they would have done well to follow. At a moment so critical he could not give Austria a fair pretence for betraying him on the occurrence of the very first reverse; this would indeed have been the height of folly in one who had risked everything upon the issue of a single campaign. But, on the other hand, the success of the expedition must have proved highly beneficial to Poland; and, in chilling the national enthusiasm at this time, the deputation were innocently instrumental in inflicting the greatest evils on their unhappy country.

Results.

This is not the place to dwell on the unexampled disasters of the Russian campaign, which were greatly aggravated by the apathy of the Poles, and their refusal to co-operate in covering the retreat of the French army. The details are in the memory of all. The work of Napoleon was destroyed; the grand duchy of Warsaw ceased to exist; the king of Saxony was stripped at once of it and of a portion of his hereditary dominions; the allied, who were also the partitioning powers, again took possession of the towns which they had held previous to the invasion of Napoleon; and in this state matters remained, awaiting the meeting of a congress, which was to assemble to decide, amongst other things, the fate of this unhappy country.

Treaty of Paris. Poland.

The negotiations which commenced with the downfall of Napoleon, and were completed by the treaty of Paris in 1814, necessarily embraced the future condition of Poland, which, though then occupied by Russian troops, had from previous cession to France become a fit subject of arrangement, not for the eventual benefit of Russia alone, but for that of the whole European commonwealth. Public opinion, the interests of rulers, and the sympathies of the governed, were all in favour of the re-establishment of the kingdom in its ancient integrity; and the side of justice, policy, and humanity was powerfully advocated by France and England, whose ministers regarded the Polish question as one in comparison of which all others were of but secondary importance. But neither of these powers, nor both of them united, were in a situation to control the views of those interested in maintaining the state of things created by the successive dismemberments of Poland. France, exhausted by long wars, and now restricted within her ancient limits, had no longer a voice potential in the decision. Britain, with the right of remonstrance, which her minister freely exercised, was in no condition to brave two great military powers; and although Austria not only expressed a desire for Polish independence, but a readiness to surrender part of her Gallician provinces in order to endow the new kingdom, yet all this might have been easily counteracted by the predominant influence of Russia and Prussia. At that period, indeed, the Emperor Alexander displayed or affected a spirit of liberality, which appears to have owed its origin to various circumstances; but whether he was sincere or the contrary, "an accident," as Madame de Stael described him, or merely the impersonation of hypocrisy and perfidy, it was certain the genius of the Russian system would govern the ultimate determinations of his policy on a subject of so much importance to his empire.

The kingdom of Poland.

At this juncture, however, Napoleon escaped from Elba, and the whole question assumed a new phasis. In the common danger, Poland was scarcely remembered; and the czar, finding that his aid would be indispensable in the approaching contest, was enabled to insist on a measure which he had long contemplated, namely, the union of the grand duchy with Russia as a separate kingdom. The facility with which he carried his object proves the alarm that had been occasioned by the re-appearance of Napoleon, and the anxiety felt to adopt any measure calculated to prevent Polish partisanship from swelling the ranks of the invader. It was therefore decided that the grand duchy of Warsaw should be attached to the empire of Russia, under the name of the kingdom of Poland, and that it should be governed by separate institutions. "The duchy of Warsaw, with the exception of those provinces and districts which are otherwise disposed of, is united to Russia. It shall be irrecoverably bound to the Russian empire by its constitution, to be enjoyed by his majesty the emperor of all the Russias, his heirs and successors, for ever." Such are the expressions employed in an article relating to this point in the treaty of Vienna. The two sovereignties were united by the constitution alone, and not otherwise. This was the connecting link which bound them together. Austria and Prussia acceded to a similar arrangement, and also agreed to confer on their Polish subjects a national representation and national institutions. The concessions required by public opinion were made, and certain bases were solemnly sanctioned by the treaty of Vienna.

Bases of the union between Poland and Prussia.

These were four in number. In the first place, Gallicia and the salt-mines of Wieliczka were restored to Austria. Secondly, the grand duchy of Posen, forming the western palatinates bordering on Silesia, and containing a population of about eight hundred thousand souls, was surrendered to Prussia; which power was also confirmed in the conquests made at the period of the first partition. Thirdly, the city and district of Cracow, about twenty geographical miles in extent, and containing a population exceeding an hundred thousand souls, was formed into a free and independent republic, under the guarantee of the three powers. Fourthly, the remainder of ancient Poland, comprising the chief part of the recent grand duchy of Warsaw, with a population of about four millions, reverted to Russia, and was to form a kingdom irrecoverably bound, by the constitution which the czar had engaged to confer upon it, to the Russian empire. "The kingdom of Poland," said the Emperor Alexander, "shall be united to the empire of Russia by the title of its own constitution, on which I am desirous of founding the happiness of the country." Thus a part of Poland was re-established as a separate state, by the act of all the powers of Europe; and although the emperor of Russia was to be king of that state, still the independence and separate existence of the kingdom were not only recognised in the fullest manner, but at the same time solemnly guaranteed.

The tution charte

The new kingdom of Poland was proclaimed on the 20th of June 1815, and on the 24th of December following a constitutional charter was granted to the Poles. The articles of this charter, by which Poland became united to Russia, were of so liberal a nature as to astonish all Europe. According to some, they prove that, at the time of their promulgation, Alexander was no enemy to liberal institutions. But the more probable supposition seems to be, that the earnest and loyal interposition of Great Britain and France, favoured by the declared disposition of Austria, and strengthened by the public opinion of Europe, had more effect on the mind of the czar than any presumed inclination towards liberal institutions, of which he afterwards became the most uncompromising opponent. The principle articles, which are now only matter of history, were as follow.

The p pal ar of this ter.

The Catholic religion was declared to be the religion of the state; but all dissidents were placed on a footing of perfect equality as to civil rights, with the professors of the established faith. The liberty of the press was recognised in its fullest extent. It was provided that no subject could be arrested prior to judicial conviction. The inviolability of person and property was, in the strictest sense, guaranteed. All public business was to be transacted in the Polish language; and all offices, civil or military, were to be held by natives alone. The national representation was to be vested in two chambers, one of senators and another of deputies. The power of the crown was not greater than seemed necessary to give due weight to the executive. All kings of Poland were to be crowned at Warsaw, at the same time swearing to maintain the full observance of the charter; and during the absence of the sovereign for the time being, the chief authority was to be vested in a lieutenant and council of state. The great public departments of the state were to be presided over by responsible ministers. The legislative power was vested in the king and the two chambers; an ordinary Diet to be held every two years, and to sit thirty days, and an extraordinary Diet to be convened whenever this should be judged necessary by the king. No member of the Diet could be arrested during a session, except for great offences, and not even then without the concurrence of the assembly. The deliberations of the Diet extended to all projects submitted to it by the ministry, affecting the laws and the whole routine of internal administration. The deliberations of the Diet were to be public, except when committees were sitting. All projects of law originated with the council of state, and were laid before the chambers by order of the king; such projects, however, being previously examined by committees of both houses. In the case of all projects or bills, the majority of votes was to decide. The senators were to be nominated by the king, and to exercise their functions during life. The deputies, a hundred and twenty-eight in number, were seventy-seven for as many districts, and fifty-one for communes, or about double the number of senators. To become a member of the second or lower chamber, the qualifications were, citizenship, the age of thirty, possession of some portion of landed property however small, and the payment in annual contributions to the state of a hundred Polish florins. No public functionary was eligible to a seat without the consent of the head of his department. The nobles of each district were to meet in dietines for the purpose of electing one of their body to the general Diet, and returning two members to the palatine assemblies, all dietines being convoked by the king. The class of electors was numerous, comprising, first, all landowners, however small, who paid any contribution towards the support of the state; secondly, every manufacturer or shopkeeper possessing a capital of ten thousand florins; thirdly, all rectors and vicars; and, lastly, all artists or mechanics distinguished for talent. The electors required to be enrolled, and to have attained the age of twenty-one years. The tribunals were to be filled with judges partly nominated by the king, and partly elected by the palatinates; the former being appointed for life, and removeable only for misconduct, or judicial iniquity, in the discharge of their functions.

Re erks th on.

Such were the principal provisions of the charter which was thus conferred on the Poles, and received by them as the first instalment of that restitution which they hoped would one day be made effectual and complete. Its greatest defect consisted in the incompetency of either chamber to propose laws, the initiative being confined exclusively to the executive, or the king and the council of state, and an effectual check thereby applied to legislative amelioration. Nor was any provision made in the charter for the establishment of trial by jury, an institution which, however suitable to our habits and modes of thinking, may not have been equally so to those of the Poles. But it is nevertheless certain that Alexander, on his return from witnessing the prosperity of this country, which he attributed in part to our judicial system, ordained the establishment of trial by jury throughout Poland within six months; being in this carried by mere impulse, without any regard to the fitness or unfitness of the institution to the wants, habits, and prejudices of the people amongst whom he proposed to naturalize it. It is not thus that national benefits are really conferred, or that new systems can ever be advantageously introduced.

Pe lly of R a. Co tan- ti

From the re-establishment of the kingdom in 1815, until the year 1820, the affairs of Poland were conducted apparently in conformity with the constitution. The benefits of the government had to a certain extent disarmed the prejudices and antipathies of the people; the opposition to ministers in the lower chamber was comparatively trifling; the emperor's lieutenant, Count Zayonczek, a Pole, endeavoured to attach the Poles to his sway; and Alexander, congratulating himself on the liberal policy which he had adopted towards his new subjects, declared in full senate at Warsaw, that he only waited to try the effect of the free institutions he had given them, in order to extend those institutions over all the regions which Providence had placed under his sway. But all this fair promise proved hollow and deceptive. From the very first there had been perpetual breaches in the constitution; and after the Spanish revolution of 1820, followed as it speedily was by the establishment of the Holy Alliance, all disguise was thrown aside, and an attempt made to suppress entirely the spirit of national independence in Poland. Count Zayonczek was only nominally the king's lieutenant. The real power was invested in the Grand Duke Constantine, who held the appointment of commander-in-chief of the army. This personage, who played so conspicuous a part in the affairs of Poland, is deserving of notice, in consequence of the position in which he was placed. Although possessed of considerable talents, he was, in fact, an untamed tiger, giving way on all occasions to the most violent paroxysms of passion. He had a strong sense of the rights of his order, and held as nought the feelings of every other class. As soon, therefore, as he found that his brother was no longer the liberal patron of constitutional rights, he gave the most unrestrained license to his natural violence and caprice. The outrages ascribed to him display a mixture of ferocity, cruelty, and cowardice, altogether unparalleled. With him no right was respected, and no condition safe. Females were insulted, abused, sometimes kicked; shaving the heads of such women as displeased him was a common occurrence; and to this was added tarring and feathering, a favourite recreation of the commander-in-chief, whose delight it was to witness these barbarities. He kept in his employment a legion of spies; and the liberty or life of every man was at the mercy of a common informer. With him suspicion was a sufficient warrant to exclude the proof of innocence, and accusation led at once to conviction.

Political tyranny superadded to private oppression.

But whilst acts of private oppression were calling forth all that hatred of Russia which is the birthright of every Pole, political tyranny was superadded, as if it were desirable to concentrate upon one point the entire indignation of a brave and devoted people. The liberty of the press was abolished, and a censorship established, in violation of article sixteenth of the constitutional charter. This was effected by an ordinance dated the 31st of July 1819; and not long afterwards the patriotic association formed by General Dombrowski, who had modelled it almost after the recommendation of Alexander, was suppressed, and a military commission appointed, which tried and condemned civilians without any of the prescribed formalities. "What have we to hope," exclaimed Dombrowski; "what have we not to fear? This very day might we not tremble for the fate which may await us to-morrow?" Meanwhile, the secret police pursued its fatal career, and arbitrary arrests, followed by hidden condemnations, the banishment of many and the imprisonment of more, signalized its hateful activity. The university of Wilna was also visited with severity by the agents of this dreaded institution. Twenty of its students were seized, and subjected to different punishments. Nor were those of Warsaw treated with greater leniency. A state-prison was likewise erected in the capital, and its dungeons were soon crowded with inmates, victims of the execrable system adopted by the government. Nor were these the only grievances of which the people had reason to complain. Although the constitutional charter had provided that Russian troops, when required to pass through Poland, were to be maintained at the sole charge of the Russian treasury, yet for years they had been stationed at Warsaw, and paid by the inhabitants of the capital, whom they were employed to overawe. Further, independently of the violations of individual liberty, the difficulty of procuring passports, the misapplication of the revenue to other objects than those for which it had been raised (as the maintenance of the secret police), and the nomination of men as senators, without the necessary qualifications, or any other merit than that of being mere creatures of the government, were infractions of the charter as wanton as they were intended to be humiliating. But the worst of all yet remains to be told. In the dietines Russian money and influence were unblushingly employed to procure the return to the general Diet of such members only as were known to care less for the honour of their country than the advancement of their own fortunes. Instead of a Diet being held every two years, in accordance with article eighty-seventh of the charter, none was convoked from 1820 to 1825, and only one from the year 1825 until after the accession of Nicolas in 1829. Finally, an ordinance issued as early as 1825 had abolished the publication of the debates in the two chambers; and on one occasion, the most distinguished members of opposition were forcibly removed from Warsaw the night preceding the opening of the Diet. Add to all this the constant irritation produced by the ungovernable temper and consequent excesses of Constantine; the useless but vexatious manœuvres he introduced into the army; his rigorous mode of exercise, exceeding the ordinary measure of human strength and endurance; his overbearing manner towards the best and highest officers in the service; and, above all, that progressive increase in cruelty which a regimen of terror presupposes and almost necessitates: take these matters into consideration, along with all the other circumstances of grievous oppression which have already been stated as affecting the mass of the people, and it will easily be seen that it was vain to whisper peace, and that the grand duke was treasuring up to himself wrath against the day of wrath.

Universal discontent. Favourable moment for rising lost. Revolution of Paris, July 1830.

It has been matter of some surprise to foreigners that the Poles did not take advantage of the Russo-Turkish war to erect the standard of independence. The reverses experienced by the Russian army on the Danube in the campaign of 1828, were so great, that an insurrection in Poland at that critical and perilous moment would have had almost every chance in its favour. But at that period the plan of the Poles had evidently not been matured. That it was even so in November 1830 may reasonably be doubted. In fact, no preparations seem to have been made, and when the explosion actually took place, it was wholly unexpected by the leading patriots, who conceived that the propitious moment had not yet arrived. At the same time it must be confessed, that the French Revolution of July 1830 produced an almost electric effect on the whole Polish nation, and, by its daring character and its splendid success, disposed the initiated to anticipate the time for a general rising. Besides, it is generally believed that emissaries from Warsaw had held confidential meetings with the leaders of the Revolution of July, and were instigated to rouse their countrymen by the promise of immediate aid from the government of the citizen king; and that such aid was confidently relied on by the Polish patriots themselves, must be known to all who have conversed with those who acted a prominent part in the national insurrection, and seems to be further confirmed by the universal impression of the people. Two other circumstances also contributed to accelerate the catastrophe. The army began to entertain a notion, not altogether unfounded, that it was to be removed to the south of Europe, to assist in extirpating freedom in France and other countries; and that its place was to be supplied by a native Muscovite force. The students of the military school likewise found ample cause of apprehension in the previous arrest of several of their number, upon suspicion of being connected with secret associations, which had for their object to promote a general rising. The repugnance of the army to the service intended for them; the apprehensions of the students, who had everything to fear from the grand duke, should he try their companions by martial law, as he had threatened to do, and most probably meditated; the conviction that the whole populace of the capital were friendly to the project of an insurrection; the secret encouragement held out by France; the eagerness of the enterprising to court danger for its own sake; the number of those who had personal wrongs or insults to avenge; and, lastly, the presumed, or rather the certain, approbation of the free in all countries towards the insurrection itself, if not towards the time and the circumstances: all these, therefore, concurred to hasten the opening of the great tragedy, the enacting of which all Europe regarded with such deep and thrilling interest.

The first object of the actors in this enterprise was to seize the person of the grand duke, their most obnoxious enemy, and to detain him as a hostage for their own safety in the event of failure. The students of the military school were the voluntary leaders of the movement, which burst forth on the 29th of November 1830. Early in the evening of that day, several of them repaired to their barrack, in accordance with a preconcerted plan; and having addressed their comrades, summoned them to take up arms. The call thus made was instantly obeyed. On their way to the residence of Constantine, who had established himself at the palace of Belvedere, in the outskirts of the city, their number was increased by the students of the university, and the young men attending the public schools. Constantine had no troops about his residence, but at a short distance from it were the barracks of three regiments of Russian guards. The hour chosen for the attack was seven o'clock, and at that time the assailants proceeded to the bridge of Sobieski, where the main body posted themselves, whilst some of the most determined pressed forward to complete their object. They forced their way into the palace, where they were first opposed by the director of the police, Lubowidizki, who, on being wounded, took to flight. Next they encountered the Russian general, Gendre, a man obnoxious for his cruelties and crimes, who was killed in the act of resisting. Lastly, when on the point of reaching the bedchamber of the grand duke, whom the alarm had just awaked from his evening siesta, they were stopped by a valet, Kochanowski, who, closing a secret door, thus enabled his master to escape undressed through a window. Constantine fled to his guards, who instantly turned out. Disappointed in their prey, the devoted band rejoined their companions at the bridge of Sobieski, where they had been awaiting the result of the attack on the palace. On finding that their first object had failed, they now resolved to gain the city, and at once proclaim a general insurrection. Their retreat was opposed by the Russian guards, close to whose barracks it was necessary to pass. But such was the spirit which animated them, such were the skill and courage they displayed, that they killed three hundred of their opponents, and triumphantly effected their retreat. On reaching the city, they instantly liberated every state-prisoner, and were joined by the school of engineers and the students of the university. A party entered the only two theatres which were open, calling out, "Women, home; men, to arms." Both requisitions were instantaneously complied with. The arsenal was next forced, and in less than two hours from the first movement, so electrical was the cry of liberty, forty thousand men of all descriptions were in arms. The sappers and the fourth Polish regiment declared early in favour of the insurrection; and by eleven o'clock the remainder of the Polish troops in Warsaw, with the exception of two regiments of guards whom Constantine had forced along with him, espoused the popular cause, declaring that their children were too deeply compromised to be abandoned. Never perhaps was any popular movement more universal or more triumphant.

By the morning of the 30th of November the commotion had subsided, and the results could be calmly surveyed. Besides the troops of the line which had joined the patriots, nearly thirty thousand citizens had taken up arms, and now swelled their dense ranks. In twelve hours the revolution had been begun and completed. In vain did the grand duke, who lay without the walls, meditate the recovery of the intrenchments and fortifications. His isolated though desperate efforts to re-enter the city were repulsed with serious loss; and finding it hopeless to contend with the mass opposed to him, he not only desisted from all further attempts of the kind, but removed to a greater distance from the walls. In the excitement consequent on this extraordinary commotion, no one will be surprised to learn that, notwithstanding the regularity with which every part of it was conducted on the part of the principal actors, some excesses were committed. But these were neither many in number nor aggravated in character; and although some Russians lost their lives, as did also several Poles, who were known to have been on terms of intimacy with Constantine, yet these men courted their fate by recklessly intermingling amongst an excited population when their passions were inflamed by the heat of battle, the tumult of victory, and the feverish excitement of revolution.

The functionaries of the government having abandoned their posts, an administrative council was immediately form-story.

ed to preside over the destinies of the new state. It consisted of men distinguished for their talents, their character, or their services, and numbered amongst its members Czartoryski, Radzivil, Niemcewicz, Chlopicki, Pac, Kochonowski, and Lelewel. But no good resulted from this heterogeneous assemblage of persons professing moderate and ultra opinions, or what may be called Whigs and Radicals. The former were not men made for revolutions, though in this instance they obtained the direction of the movement; and, in the hope of accommodation, which, from the first, was desperate, they allowed the grand duke to retire under a convention, when they might have captured his entire army, and detained himself as a hostage. At first they evidently entertained no intention of throwing off their allegiance to the czar. All their proclamations ran in his name, and their claims were confined to a due execution of the charter. On the part of the provisional government, however, this seems to have been the very excess of weakness. Men who engage in revolutions, if they hope or wish to succeed, should, when they draw the sword, throw away the scabbard. Besides, as nothing less than unconditional submission would gratify the czar, it is obvious that negotiation was at once a waste of time, and a confession of indecision. The next blunder of the council was in the opposite direction. As their patriotism appears to have risen with their success, they at length insisted on the incorporation of Lithuania, and the other Polish provinces subject to Russia, with the kingdom; and, as if this had not been enough, they some months afterwards declared the throne vacant, an act which, upon their own principles, was equally rash and impolitic. But, what was worst of all, they lost precious time. The force of the first impulsion was wasted. The great and sudden outburst of national enthusiasm was allowed to exhaust itself. Russia had been braved at a time when all her energies might be concentrated to enforce submission; when neither foreign war nor domestic disturbance distracted her councils or divided her means; yet, so far from profiting by the only advantage resulting from the wild improvisation so rapidly nationalized, the provisional government acted as if their sole object had been to forego the chances which the national movement had, in the first instance, accumulated in their favour.

But all these errors were nobly redeemed. When it appeared that negotiation was vain, and that nothing but unconditional submission would satisfy the czar, they gallantly prepared themselves for the unequal struggle. Their plans were evidently not matured. Neither from Lithuania, nor from any of the other Polish provinces incorporated with Russia, did they receive the aid on which they had relied; yet the honours of the first campaign were exclusively their own. Their efforts were stupendous, and their bravery was worthy the age of Boleslas and Sobieski. The laurels which Diebitsch Zabalkanski had reaped in his campaign against the Turks, protected by mountains and fortresses, were blighted and withered in the plains of Poland. On the 25th of February 1831, his dense masses, first brought into contact with the patriotic forces at Grochow, recoiled from the shock, after one of the most unequal and sanguinary conflicts of modern times. March was illustrated by the victories of Dembewielki and Wawr; and in May was fought the celebrated battle of Ostrolenka, where, after performing prodigies of valour, the Polish army retired from the field, unpursued, towards Modlin. In the mean time, Diebitsch had perished, the victim of disease, chagrin, and fatigue. Paskewitsch, distinguished by his Armenian campaigns, succeeded, and, following the example of his predecessor Suwarof, concentrated all his means for an attack on the capital. On the 5th, 6th, and 7th of September was fought the ever-memorable battle of Warsaw, which ended in the defeat of the patriot forces, and the loss of that city, after a struggle unparalleled in history. This blow proved decisive. European interference had been hoped for, but in vain; the faith of treaties had been appealed to without effect; the interests and the sympathies of the civilized nations of the west and the south had been invoked to no purpose. A powerful force still remained, and, for a time at least, a partisan warfare might have been carried on; but thus abandoned to its own resources, Poland must at last have yielded to her gigantic antagonist. That country had no mountain fastnesses, where her children, when overpowered by numbers, might take shelter; it had no fortresses capable of arresting and breaking the force of her assailants. Nothing could have saved her but a prompt and active interposition, founded on the treaty of Vienna; and such was the situation of France and England at the time, that neither judged it safe or expedient to interfere, otherwise than by remonstrance. What then remained, but the miserable alternative of submission or annihilation?

The Poles did submit. With reluctance they laid down those arms, which they had taken up in the hope of reconquering their national independence, and which they had so gloriously employed in many a hard-fought field. But all former experience of Muscovite vengeance could scarcely have prepared them for the miseries which have since been accumulated, in new and fearful forms, on their unhappy country. To say nothing of proscription and confiscation, her plains have been covered with ruins, her resources exhausted, her industry and commerce destroyed; abundance has given place to wretchedness and want; the countenances of her children, once so happy, are now wan, squalid, and despairing; she has no longer a name or a place amongst the nations; her language, her literature, and her history cannot any more be publicly taught in her schools; terror reigns throughout all her borders; and the victorious czar, using the utmost license of success, has even attempted to break down the ineffaceable distinctions of race, in the hope of destroying that sentiment of nationality which is part of the inheritance of every Pole. And all this has been done, or is now doing, in the face of the public guarantee of the powers of Europe, if not without remonstrance, at least without any effectual opposition, and with a systematic perseverance and determination which in time must produce a marked and decisive change in the national character of the people.

The history of the little republic of Cracow forms an appropriate sequel to that of the unhappy kingdom of Poland. That small state, created by the treaty of Vienna, and having its independence guaranteed by the same general compact, enjoyed the constitution which had been conferred on it by the three powers, until the year 1835, when, on the most frivolous pretences, it was occupied by the troops of these powers. A greater outrage against every principle of public law or public faith was never probably perpetrated. But, as in the case of the kingdom of Poland, the crime has been committed with complete impunity; and we are now given to understand that the military occupation of the republic is to be followed by its dissolution, and the last remnant of Polish independence thus annihilated. This proceeding needs no comment expository of its real character. It is an act of naked despotism, done in defiance of the other powers of Europe, and in open contempt of the most sacred principles of public law and public justice.

STATISTICAL VIEW OF POLAND.

Population.

Population.

The valuable work of Mr Stanislas Plater, published at Posen in one volume octavo, under the title of *The Geography of the East of Europe*, gives the best and most elaborate statistical description of all parts of the ancient kingdom of Poland that has yet appeared. There have been

Population.

more recent works (Mr Plater's having appeared in 1825), but we are not aware of the existence of any on which the same reliance can be placed. It is accordingly from it that the following particulars have, in a great measure, been compiled.

1. In West Prussia, formed by the first partition of Poland under Frederick II., we find, on a space of 400 square Polish miles, a population of 700,000 inhabitants, viz. 350,000 Poles, 330,000 Germans, and 20,000 Jews; of whom 320,000 are Catholics, 350,000 Protestants, 20,000 Israelites, and 10,000 Menonites. West Prussia is divided into two subdivisions; that of Dantzig, which contains eight districts, and that of Marienwerder, which comprises thirteen.

2. The grand duchy of Posen, as it now exists, with the boundaries of the surrounding states as fixed by the treaty of Vienna, contains, on 540 square miles, a population of 980,000 inhabitants, viz. 640,000 Poles, 270,000 Germans, and 70,000 Jews, of whom 580,000 are Catholics, 330,000 Protestants, and 70,000 Israelites. The grand duchy of Posen is divided into two subdivisions; that of Posen, which includes seventeen districts, and that of Bromberg, comprising ten districts.

3. The kingdom of Gallicia, as at present annexed to the Austrian dominions, on a space of 1500 square miles, contains 4,000,000 inhabitants, viz. 1,700,000 Poles, 1,800,000 Rusniaks, 150,000 Walaques, 50,000 Germans, and 300,000 Jews, of whom 1,480,000 are Catholics, 2,000,000 Greek Catholics, 200,000 Russo-Greeks, 20,000 Protestants, and 300,000 Israelites. The kingdom of Gallicia is divided into nineteen districts.

4. The republic of Cracow, whilst it existed, contained, on a space of twenty square miles, a population of 120,000 inhabitants.

5. The kingdom of Poland, as established by the treaty of Vienna, contained, on a space of 2270 square miles, a population of 4,128,289, of whom 3,440,357 were Roman Catholics, whilst the remainder, 787,930, belonged to other religions. Of these, about 3,000,000 were Poles, 200,000 Lithuanians, 100,000 Rusniaks, 300,000 Germans, and 400,000 Jews. The population of the towns is to that of the country as one to five; in other words, there live in villages 3,200,000, and in towns 887,000. This kingdom was divided into eight palatinates, thirty-nine circuits, and seventy-seven districts.

6. Russian Poland, comprising Lithuania, Samogitia, White Ruthenia, Volhynia, Podolia, and Polish Ukraine, contains, on a surface of 7600 square miles, 8,800,000 inhabitants, viz. 700,000 Poles, 880,000 Lithuanians, 5,520,000 Rusniaks, 180,000 Russians, 50,000 Tartars, 120,000 Lettons, 50,000 Moldavians, and 1,300,000 Jews; of whom 2,400,000 are Roman Catholics, 1,640,000 Greek Catholics, 3,233,000 Russo-Greeks, 180,000 Raskolniks (old Russian sectaries), 50,000 Mahommedans, and 1,300,000 Israelites. Russian Poland is divided into the governments of Wilna, Grodno, Minsk, Volhynia, Podolia, Kiow, Mohilew, Witebsk, and the province of Bialystok, comprising four districts.

7. Courland and Semigallia, an integral part of the republic of Poland until the epoch of its dismemberment in 1795, forms, in the actual political state of the Russian empire, the government of Courland, which, on a surface of 450 square miles, contains 600,000 inhabitants, and comprehends ten districts.

It thus appears that, on a surface of about 13,000 Polish square miles, there is a population exceeding 20,000,000. But a much higher estimate is given in the *Polish Monthly Magazine*, which states the superficial extent of Poland at 28,276 geographical square miles, and the population at 33,962,235, or nearly 14,000,000 more than the number above mentioned. The latter, however, so far exceeds every other estimate we have seen, that there is reason to believe it to be greatly exaggerated.

From the numerical statements above given, we find, that no inconsiderable portion of the population of Poland consists of Jews. Their first settlement in that country took place in the tenth century, when they removed thither from various parts of Germany and Bohemia, to escape persecution. In 1264 Boleslas II. granted to them a charter, which was afterwards renewed and greatly amplified by Casimir the Great. Their treatment has varied according to the temper of the times, the character of the reigning sovereign, and the degree of hatred borne towards them at particular periods. But the circumstance which has most surprised the Poles is the numerical increase of this people, whose fecundity, compared with that of Christians, is said to be as two or even three to one. Sigismund Augustus was astonished at this fact; and other sovereigns have been apprehensive that they would in time outnumber the Christian population. It has always been the policy of the Jews to conceal their numbers, by every means in their power; and it seems quite certain that every return yet obtained is much below the truth. There is no trade too vile, or even too dangerous, for a Polish Jew, provided he can profit by it. In 1806 and 1812, they were hired as spies of the French and Polish armies; and they are charged, we fear on good grounds, with betraying their employers whenever they found it their interest to do so. To the Russians, whom they were employed to watch, they rendered far more signal services than either to the French or the Poles; and their perfidy in this particular is believed to have greatly aggravated the disasters of the retreat from Moscow. The amazing fecundity of the Jews has been ascribed to their early marriages; most of them being parents at a very early age, and grandfathers before many Englishmen even think of marrying. But it may very reasonably be doubted whether early marriages are favourable to population; though there can be no question, that one consequence resulting from them is the deterioration of the offspring. In Poland, the proportion they bear to Christians is viewed with alarm, because they are not producers, but live on the produce raised by others; and it is loudly proclaimed by all the native writers, that they have been a curse to the country.

Commerce and Agriculture.

Commerce and Agriculture.

The insignificance of the actual commerce of Poland is no doubt owing to her political position. In former times, the natural resources of the country, and liberal commercial regulations, opened a wide field for the activity and enterprise of foreign merchants. During the fourteenth, fifteenth, and sixteenth centuries, Poland not only carried on a lucrative commerce with the Levant, the Black Sea, and the Mediterranean, and maintained a commercial intercourse with the Italian republics, particularly Venice; but she also exported her corn and other raw materials to the western countries of Europe, especially Holland, Sweden, and Denmark, and formed an entrepôt of oriental merchandise for the northern part of Germany and the countries adjoining. Owing to their commercial activity, Cracow and Dantzig were at an early period admitted into the Hanseatic League.

Besides wood, flax, tallow, and some other products, corn has always been the principal article of export. According to Cellarius, who wrote in the sixteenth century, the amount of corn exported in one year was 10,950,000 korzec, or 4,380,000 English quarters. Opalinski, a writer of the seventeenth century, states, that in his time, Dantzig alone received from the interior of the country more than 6,000,000 korzeg, or 2,400,000 English quarters, of different kinds of grain for exportation. The importation of foreign produce was of course proportioned to the exportation of home produce; and it was abundantly supplied to Poland both by national and foreign bottoms. Holland and Venice were extensively engaged in trade with this country. But with the political misfortunes of Poland its commercial importance declined; and its destruction has been completed in consequence of the system of monopoly pursued by the governments of Russia, Prussia, and Austria. In that part of Poland which is under the dominion of Russia, the consumption of every article of foreign produce is strictly prohibited, and every branch of industry is discouraged; whilst the governments of Austria and Prussia overwhelm their Polish subjects with disproportionate taxes, in the hope of thereby retaining them in more complete subjection. The consequence is, that the farmers have no motive or interest to produce more grain than they require for their own consumption; and hence, if any unforeseen contingency should occur, a famine must ensue. During the last few years this has actually happened in some parts of Volhynia, Podolia, and the Ukraine; countries the soil of which is perhaps the most fertile of any in Europe.

The trade of Poland is at present almost entirely in the hands of Jews and Russians. The exportation of corn, flax, wood, or any other article, whether by the Baltic or the Black Sea, can only be effected by these two classes, who, from the condition of the country, possess an entire monopoly, and being often directly assisted by the government, can fix any price which they deem proper to exact. And as regards importation, no produce can be introduced into Poland, except from Russia, Prussia, or Austria, or after having paid a transit duty amounting to a prohibition. Thus the part of Poland under the dominion of Russia must receive from the Russian manufacturer calicoes and all other cotton goods, beet-root sugar, cutlery, glass-work, paper, tea and coffee, salt (which is obtained from the Polish salt-mines of Wieliczka, now in the possession of Austria, but the trade in this article is, in Russian Poland, a monopoly held by the government), salt fish, and other articles. The case is precisely the same in those parts of Poland which are respectively under the dominion of Austria and Prussia. Every English or French article, and all colonial produce destined for Poland, is subject to a heavy transit duty at Dantzig, at Odessa, or on the Austrian frontier.

Poland has never been, and never will be, a great manufacturing country. Her natural resources consist in the produce of her soil, and her commerce in exchanging these for the cheaper and superior manufactures of other countries. With more than 80,000 square miles of fine wood; with the richest mines of salt Europe possesses at Bochnia and Wieliczka; with the fertile plains of the Ukraine, Podolia, Volhynia, and Landomierz, with the flax of Samogitia, so much employed in the English manufactures, the wool of Great Poland imported into Saxony, fine cattle and horses, abundance of tallow and other products; Poland possesses resources which leave no doubt that, under a good government, she will one day become, not indeed a manufacturing, but certainly one of the most commercial nations of Europe.

Literature and Science.

Before the introduction of Christianity, in the ninth century, the Polish language could boast of numerous traditional tales, warlike songs, and pastoral poems, which have been collected by Wodrich, and show that this language, having already attained to some degree of perfection, had consequently taken the lead of almost all the other Sclavonic idioms. It is no doubt true that the introduction of Christianity at first retarded the natural improvement of the language, by an admixture of foreign terms; but it enlarged and purified the ideas of Polish writers, and opened a new and attractive field for their talents and genius. It may appear surprising to some, that from the ninth till the end of the sixteenth century, Poland should have produced such a number of writers in the native idiom and in Latin; especially considering the continual wars in which she was engaged for the defence of her frontiers. But the wonder will cease when it is known that schools and colleges were then thrown open to every one; that education was eagerly sought after and freely imparted; that the order of St Benedict, assisted by other religious communities, devoted their whole time and attention to the gratuitous education of every class, implanting in all a love of science and literature, a taste for the arts, a knowledge of the classics, and an affection for the muses; and that, under these same orders, the youth of the country were, both by precept and example, trained up to the practice, and excited to aspire to everything that was liberal, generous, and manly. Hence, prior to the foundation of the university of Cracow, which took place during the reign of Casimir the Great, in 1347, and preceded that of the universities of Prague, Vienna, and Leipzig, Poland possessed several historians, and other learned men, whose writings still survive to attest the early cultivation of literature in that country.

Amongst these the first place is due to the chroniclers. Gallus wrote his Chronicle of Poland between 1110 and 1135. Matthias Choleva, bishop of Cracow, who wrote a chronicle of Poland, died in 1165. Kadlubek Vincent, born at Cracow in 1160, enjoyed the favour of Casimir surnamed the Just, and officiated as tutor to Leszek the Fair. He wrote his chronicle under the title of *Historia Polonica*, which was first published in 1612. Godislas Reszko, dean of Cracow, composed Annals of Great Poland. Martinus Polonus is known by his numerous writings, and particularly by his Chronicles of the Popes and Emperors. He died at Bologna in 1278. To this period also belong several men of science. Amongst these may be mentioned Octavian Wolener, of Cracow, an architect, who, a little before 1044, was invited to Vienna, to erect the church now called St Stephen's. Ciolek, in Latin *Vitellio*, a native of Cracow, was celebrated as a naturalist and mathematician. He lived in the middle of the thirteenth century, and was considered as having contributed to improve and extend the science of optics. His works were printed for the first time at Nuremberg, in 1533, under the title of *Vitellionis Perspectivæ libri decem.*

But whilst the intellectual superiority of Poland at this period was owing to her frequent and direct intercourse with Italy, it is to be observed that after the foundation of the university of Cracow, about the middle of the fourteenth century, she herself became the centre and source of civilization to the neighbouring nations. From this time Hungarians, Bohemians, Germans, Swedes, and Danes, who formerly used to repair to Italy for study, resorted almost exclusively to the university of Cracow. Of those who added celebrity to the university, there were some whose reputation was not confined to their own country. George of Sanok, born about 1400 and died in 1477, was first professor of moral philosophy in the university of Cracow, and afterwards archbishop of Leopol. His biography was written by Buonacorsi, surnamed Callimachus, a celebrated Italian philosopher. John of Glogau, born in 1440 and died in 1477, was also a professor in the university of Cracow, and left numerous manuscripts on different subjects, but mostly on the Aristotelian philosophy, several of which were afterwards published. Dlugosz, in Latin *Dlugossius*, born in 1415 and died in 1480, was a statesman and historian. As great treasurer of Poland, he, on many occasions, rendered important services to his native country; he also protected science, established hospitals, and founded an exhibition or bursary in the university of Cracow. Of his numerous writings, the most important is his History of Poland. Brudzewski, born in 1445 and died in 1497, studied at Cracow, and afterwards became professor of mathematics in that university, where he had the distinction of being the master of Copernicus. He left several works, the principal of which treat of astronomical subjects and the construction of the astrolabe. Nicolas Copernik, called in Latin *Coper-*

nicus, born in 1473 and died in 1543, studied at Cracow, and by divining through the mists of error, rendered venerable by time, the true system of the world, established for himself a name which will live whilst sun and moon endure. Martin of Olkusz, the school-fellow and friend of Copernicus, died in the year 1530.

These men, however, with all their individual merits, were only the precursors or harbingers of a period of higher excellence and greater refinement. Free at home, and powerful abroad, Poland, during the sixteenth century, occupied a distinguished place amongst the states of Europe; and the period of her political glory was also the golden age of her literature. Amongst the poets of this period the first place belongs to John Kochanowski, born in 1530 and died in 1584, who is justly regarded as the father of Polish literature. He was the author of works both lyrical and dramatic, and translated Anacreon, Horace, some parts of the Iliad, and also the Psalms of David, which are remarkable for purity and vigour of style. Rey of Naglowice also wrote several works in verse and prose; whilst Peter Kochanowski left translations of Tasso's *Gerusalemme Liberata*, and Ariosto's *Orlando Furioso*, which were printed at Cracow in the year 1618. Miaskowski, Sarzynski, Rybinski, Grochowski, and Klonowitz, were likewise eminent as poets. As prose writers may be mentioned, Michowita, who wrote several important works, particularly on Polish history; Kromer, the son of a peasant, who by his talents obtained the highest ecclesiastical dignity in Poland (that of Prince-Bishop of Warmia), and left important works on the history of his country; Bieliski, who wrote on subjects of moral philosophy and history; Gornicki, an eminent writer on politics and history, and whose style is remarkable for its purity; Stryjkowski, a poet and historian; and Orzechowski, an apostate priest, but a distinguished writer and speaker, who, by his defence of the principles of the Dissidents, attracted the notice of Pope Julius III., with whom he maintained a long and animated controversy.

This period also produced several men distinguished in law, ethics, mathematics and astronomy, the natural sciences, medicine, and agriculture. Amongst the lawyers and jurisconsults may be mentioned Herbert, secretary of Sigismund Augustus, who published a collection of statutes and privileges; Malecki, who wrote a book entitled *The Lawful Marriage of Bishops, Priests, and Monks;* Groicki, a civilian of eminence, the author of a work on the statute law of Magdeburg; besides Ianuszewski, Lazarowitz, and Smiglecki. In ethics, Rey, Koszucki, and particularly Petrycy, distinguished themselves, though in different degrees. Petrycy translated the *Ethics* of Aristotle, and also the *Policy* of the same author, which he published at Cracow in 1618, along with his own commentaries. In mathematics and astronomy, Poland could boast some of the most distinguished men of the age; but as most of them published their works in Latin, it is only necessary to mention here those who wrote in Polish. These were Klos, author of a treatise on Arithmetic, published at Cracow in 1538; Grzebski, professor in the university of Cracow, whose works on Geometry were published in 1656; and the astronomers Latos, Rosciszewski, Zebrowski, and Bernat. Nor were the cultivators of the natural sciences either few in number or inferior in zeal and knowledge. Amongst the more eminent may be mentioned Spiezynski, who wrote several works on Botany, published at Cracow; Martin of Urzadow; Falimierz Syrenski, professor of medicine in Cracow, whose work on the properties and uses of plants, published after his death, is highly esteemed; Peter of Kobylny, Andrew Glader, Valenti of Lubiin, Oleszko, and Umiastowski, skilful physicians, who published important works on different maladies; Trzecieski, author of several works on agriculture and husbandry, published at Cracow in 1540 and 1571; and Dubrawski, whose work on fishes, published in 1600, is still considered as a work of great merit. There were also during this period several writers on the art of war, amongst whom may be mentioned Strubiez, Paprocki, and Cielecki.

This, the golden age of Polish literature, continued from the middle of the fifteenth until the commencement of the seventeenth century. But from the reign of Stephen Batory in 1586 we may date the temporary decline of Polish literature, and the corruption of the Polish language. During the seventeenth century the introduction of the Latin language into official transactions, and the great political crisis which Poland had to undergo, obstructed the tendency of the national literature, and directed the energies of the Poles towards one great object, namely, the preservation of their political existence. Amidst growing internal disorder, at once the cause and the effect of national calamity, the peaceful pursuits of science were neglected; and under the two princes of the house of Saxony, Augustus II. and his son Augustus III., Poland sunk into a state of both political and intellectual degradation; nor was it until towards the end of the eighteenth century that the national mind awakened from its long trance, and a reform was effected which has since produced good fruit. Whilst Konarski and a few others began to combat that maccaronic mixture of Latin and Polish which was then so much in fashion, a number of distinguished men, such as Krasicki, archbishop of Warmia, a poet and political writer; Naruszewicz, archbishop of Luck, a poet and historian; the two brothers Augustus and Michael Czartoryski, Albertandy, Zamojski, Potocki, Kollontay, Czacki, and many others, opened a new career for Poland; and by the impulse thus given the regeneration of literature was assured, although the liberties of the nation have been destroyed.

The first place amongst modern Polish writers is commonly assigned to John Paul Woronicz, born in 1757 and died in 1829, the archbishop of Warsaw, metropolitan primate of the kingdom of Poland, and an eminent poet and prose writer. Julian Ursyn Niemcewicz, distinguished alike as a poet, an historian, and a statesman, has been elevated by his tales to a high place amongst modern Polish writers; whilst in some of his other productions, particularly his *Powrot Posla*, or the Return of a Deputy to his Home, he has exhibited a most lively and animated picture of Polish habits and manners. Karpinski is the Burns of Poland; and Brodzinski, Felinski, and Ossolinski, are likewise popular poets. Of the patriotic bards, Adam Mickiewicz is the head and prince. His effusions are generally of a plaintive character, except when they dwell with rapture on the past glories of Poland. The muse of freedom is indeed the idol of his poetical worship; and, like Schiller and Goethe in Germany, Byron and Moore in England, Lamartine and Delavigne in France, he has taken from the altar of liberty that hallowed fire the divine flame of which warms and animates his strains. Lastly, in the class of modern historical writers, no one can claim precedence of Joachim Lelewel, a name venerable in literature, and honourably known for his strict regard to truth, and the liberality of his political writings.

Lastly, in closing this survey, a melancholy feeling is awakened in the mind. We are in fact writing of the past, without almost any reference to the present. Since the failure of the insurrection of 1830 and 1831, literature may be said to have expired in Poland, or rather to have been destroyed by the barbarous despot who has sought to proscribe her history, and even to eradicate her language; but amongst the exiles there are many men of distinguished literary acquirements, whose talents and learning enable us to form a tolerable estimate of the general state of education in their native country previously to the revolution; and we know from history that high mental cultivation has long co-existed in Poland with that chivalrous heroism for which they have always been pre-eminently distinguished.

(A.)

POLAR SEAS.

Seas,

THE rapid progress which has been made within the last half century in physical science and geography, has thrown a deeper interest on whatever concerns the polar regions, than belongs to the mere commercial speculation in which originated the earliest attempts for discovering a passage through the North Polar Ocean to India and China. It is not here intended, however, to enter into any detail concerning the new objects of natural history, the atmospherical phenomena of temperature, electricity, and magnetism, and various other points of scientific research, which the late expeditions have been the means of collecting and communicating; but to exhibit a sketch of the various attempts which have been made to explore those regions of darkness, long supposed not only to be uninhabitable, but unapproachable, and to take a very concise view of the progressive discovery and geographical information which have resulted from those attempts.

NORTH POLAR SEA.

B daries an xtent of e N a Po- lar ea.

We are now able to draw, with nearly geographical accuracy, the boundaries of the North Polar Sea. A very large portion of the northern shores of Europe, Asia, and America, which circumscribe it, have been visited; and the position of most of their bays, headlands, and rivers, geographically ascertained. By casting our eye over the north polar chart, it will be seen that the Polar Sea of that hemisphere is an immense circular basin, which communicates with the two great oceans of the world, the Atlantic and the Pacific, by two channels, the one separating America from Europe, and the other America from Asia. It will be seen that few points of the coasts of Europe and Asia, which occupy a full half of the circumscribing circle, extend much beyond the seventieth parallel of latitude; and all these points have been passed by water, though at different times and by different persons, with the single exception of the Cape Cevero Vostochnoi, which, on the charts, is made to extend to the latitude $75\frac{1}{2}$°. The northern coast of America, with Old Greenland, and the two channels above mentioned, complete the circle, America extending about 80° of longitude, or just two ninths of the whole circle; and of this portion the whole coast has now been ascertained, with the exception of that part which lies between Cape Turnagain of Franklin, and the land at the bottom of Prince Regent's Inlet, which the gentlemen of the Hudson's Bay Company are now (1838) exploring. This being accomplished, we shall have the whole line of the northern coast of America completed. We may therefore state, that the average of the degree of latitude of this coast is about the same as, or rather lower than, that of Europe and Asia, and the extent of the North Polar Sea may be considered as about 2400 geographical miles in diameter, or 7200 in circumference.

Isl s of this a.

The interior or central parts of this sea are very little known. Several islands are scattered over its southern extremities, the largest of which is Old Greenland, whose northern limit has not yet been passed; the others are, Spitzbergen, Nova Zembla, the islands of Liakhov, or, as some have been pleased to call them, New Siberia; the North Georgian Islands of Parry, and those which form the western land of Baffin's Bay; to which may be added the Boothia Felix of Ross, which there is little doubt is an island. Besides these, there are a number of small alluvial islands formed at the mouths of the several rivers of the two continents; but whether any, or what number of islands may exist nearer to the pole, we must of course remain ignorant till the Polar Sea has been further explored.

Polar Seas.

Object of early voyages to the north. Iceland, Greenland, &c. discovered.

For the little which is known of this sea, we are indebted to that spirit of discovery which showed itself immediately after a passage to the East Indies had been effected round the Cape of Good Hope; not so much, it is true, for the sake of geographical discovery, as that of shortening the passage by sea to the eastern parts of the world. It was obvious that, if a ship could proceed from the Atlantic to the Pacific, on a great circle of the sphere, or nearly so, the distance, compared with the circuitous passage round Southern Africa or Southern America, would be prodigiously shortened. The voyage of Columbus had that object; but it was soon discovered that, from the Straits of Magelhaens to the Gulf of St Lawrence, there was one uninterrupted continuity of land. Of the northern regions, the information obtained has been scanty and discouraging for such an enterprise. One of the Scandinavian pirates had indeed been driven by stress of weather, as early as the middle of the ninth century, upon an island to the north-west, to which, from its appearance, he gave the name of Snowland, which was afterwards changed to that of Iceland by the leader of the Norwegian colonists who took refuge on that inhospitable spot; but it was not till more than a century after this that Eric Rauda discovered the southern part of Old Greenland; and there are grounds for believing that, in the year 1001, some of these colonists discovered Newfoundland and the coast of Labrador.

Greenland colonies.

The colony of Iceland continued to flourish in spite of the storms and tempests, the chilling temperature, the earthquakes and volcanoes, which shook to its centre this *Ultima Thule* of the inhabitable world; but the Greenland colonies were less fortunate. For some time that on the west is said to have succeeded so well as to number one hundred villages, divided into four parishes; but having engaged in hostilities with the natives, whom they named *Skrælings* (the same people as the present Esquimaux), the latter compelled them to abandon their settlements. The eastern colony is supposed to have shared a more deplorable fate; a stream of ice having fixed itself to the coast, about the year 1406, and rendered the whole of it, from that time to this, utterly inaccessible. The existence, however, of any such colony has of late years been called in question; and it is now supposed that all the Danish and Norwegian settlements were confined to the western side of Cape Farewell.

The voyages of Nicolo and Antonio Zeno, and of the Portuguese.

The voyages and adventures of the two brothers Nicolo and Antonio Zeno in 1380, though they added but little to the knowledge of northern geography, are extremely curious, and throw considerable light on the state of Greenland, Labrador, and the Feroe Islands (Friesland), at that early period. It may be doubted, however, if any of the voyages hitherto made were undertaken for purposes of discovery and the benefit of navigation. The Portuguese have unquestionably the merit of being the first to send out expeditions with these views; and it is to their successful discovery of a passage round the Cape of Good Hope that we owe the bold enterprise of Christopher Colon, better known as Columbus, to find out a passage to the East Indies by steering directly to the westward.

Of John Cabota.

It was not till the year 1496 that England was engaged in nautical discoveries. In that year, Henry VII. encouraged John Cabota, a citizen of Venice, to make discoveries, by granting him a patent to search for unknown lands, and to conquer and settle them. His son Sebastian, either alone or in company with his father, discovered Newfoundland, to which was given the name of *Prima Vista*, "the first seen." We say *discovered;* for although the testimonies are in favour of the Scandinavians having settled colonies upon this island, no vestige then remained or has since been found of any such colonies. The object of the voyage was, as stated by himself, that, "understanding, by reason of the sphere, that if I should sail by way of north-west, I should by a shorter tract come into India, I thereupon caused the king to be advertised of my devise, who immediately commanded two caravels to be furnished with all things appertaining to the voyage." He states in his report that he reached the fifty-sixth degree, but finding no opening in the coast, he despaired of a passage, and returned.

Of the Cortereals.

A claim, however, has been set up for the discovery of *Terra de Bacalhaos*, or the Land of Codfish, afterwards called Newfoundland, by John Vaz Costa Cortereal, a Portuguese gentleman belonging to the household of the Infanta Don Fernando, who is said to have touched at that island in the year 1463 or 1464, in an attempt to find a route to India and the Spice Islands by sailing westward round the northern extremity of America. This claim rests on the testimony of Cordeira, and on a patent commission, granting to Cortereal the captaincy of Terceira, in 1464, as a reward for his important discovery. The Portuguese certainly not only fished on the banks, but formed establishments on the island of Newfoundland, towards the end of the fifteenth century.

In the summer of 1500, two ships sailed from Lisbon, under the command of Gaspar Cortereal, on northern discovery. According to Ramusio, they arrived at a region of extreme cold; and, in the latitude of 60° north, discovered a river filled with ice, to which they gave the name of Rio Nevado, that is, Snow River. This land was Labrador, which on an old chart is named Corterealis. In returning he discovered the Gulf of St Lawrence. Gaspar Cortereal was so satisfied of the existence of a north-west passage to India, that he again left Lisbon in May 1501 with two vessels; but his own was separated on the coast of Terra Verde, and never more heard of. A second brother went out the following year, but his ship was also supposed to be lost, and all hands perished. A third expedition was sent out in search of the unfortunate navigators, but no tidings could be obtained of their fate.

Of Auberton Cartier.

The French are the only maritime people who have seen, with apparent indifference, the exertions made by other nations for the discovery of a passage to India either by the north-east or the north-west. Auberton Cartier's voyages to Newfoundland and the Gulf of St Lawrence, between 1508 and 1534, can hardly be considered as voyages of discovery; and the subsequent voyages of Roberval and of the Marquis de la Roche had no other object than the discovery of gold, or of a desirable spot for establishing a colony on the coast of America.

Of Estevan Gomez.

In the year 1524, the jealousy of the Spaniards would seem to have taken the alarm at the attempts which were making by other nations to discover a shorter way to China and the Indies by the north; for it appears that a skilful navigator who had been with Magelhaens, of the name of Estevan Gomez, sailed in that year from Coruña, with the view of discovering a northern passage from the Atlantic to the Moluccas. Gaspar, the only author who has recorded this voyage, enters into no details; but it is supposed he reached no farther than the coast of Labrador, from which he brought away some of the natives. On his return he was asked by a friend what success he had met with? The answer was *esclavos* (slaves), which the inquirer mistook for *clavos* (cloves), and spread the report of his having made, as Purchas calls it, a "spicy discovery." It is evident, however, that his voyage was a complete failure, of which, as the voluminous compiler just mentioned observes, "little is left us but a jest."

Of th Span on the coast Ameri

The alarm of the Spaniards spread to the Pacific; and Cortez, the conqueror and viceroy of Mexico, on receiving intelligence of the voyages of the Cortereals, fitted out three ships, under the orders of Francisco Ulloa, to look for the supposed Strait of Anian, through which they were to pass. In 1542, the viceroy Mendoza sent one expedition by land and another by sea from Mexico to the northward. No discoveries were made by any of these voyages. Two years after this the court of Spain ordered another expedition along the western coast of America, the conduct of which was intrusted to Juan Rodrigues de Cabrillo, a Portuguese in the service of Spain. He reached the latitude of 44° N., and gave the name of Cape Mendocino to the land, about the latitude 42° N., in compliment to the viceroy.

First lish vo

England in the mean time was not inactive. At the suggestion of Mr Robert Thorne of Bristol, King Henry VIII. caused to be sent forth "two faire ships, with divers cunning men, to seek strange regions," which left the Thames in 1527. All that Hakluyt could discover of these ships and the cunning men was, that the name of one of them was Dominus Vobiseum, and that a canon of St Paul's of London, a great mathematician and wealthy man, went on the expedition. One of these ships was cast away in the great opening between the north parts of Newfoundland and Meta Incognita, supposed to be Greenland.

Secon Englis voyag

In the year 1536, two ships, the Trinitie and the Minion, were set forth by Master Hore of London, "a man of goodly stature and of great courage, and given to the studie of cosmographie." Six score persons, we are told, embarked on this expedition, whereof thirty were gentlemen. They reached no higher than Newfoundland; but there is a curious account of their proceedings by Hakluyt, which he procured from Mr Oliver Dawbeny, merchant of London, who was one of the adventurers on board the Minion.

Voyag Sir H Willou by.

On the return of Sebastian Cabot to England, he was constituted Grand Pilot, and "Governor of the Mysterie and Companie of the Merchants Adventurers for the Discoverie of Regions, Dominions, Islands, and Places unknown." At his suggestion a voyage was undertaken, in the year 1553, for the discovery of a *north-east* passage to Cathaia, consisting of three vessels, the crews of which, including eleven merchants, amounted to 113 persons. Numerous candidates stood forward for the command of this expedition; but Sir Hugh Willoughby was appointed captain-general of the fleet, "both by reason of his goodly personage (for he was of tall stature), as also for his singular skill in the services of warre." The fate of this expedition was most disastrous. Sir Hugh Willoughby, with his brave associates, as well as the crew of the second ship, to the number of seventy persons, miserably perished from cold and hunger on the coast of Lapland, at the mouth of a river called Arzina, not far from the harbour of Kegor. The third ship, under Master Richard Chancelor, had parted company, and, by putting into Wardhuys, in Norway, escaped the fate of his companions; and in the following year discovered the port of Archangel, and opened the first intercourse with Russia.

Of Ste Burrou

In the years 1555 and 1556, two ships were sent out to Archangel to carry commissioners to the court of Moscow, and, having landed them, to prosecute discoveries, and "to use all wayes and meanes possible to learne howe men may passe from Russia, either by land or sea, to Cathaia." Stephen Burrough, in the Serchthrift, proceeded easterly as far as the island of Waygatz, where he was stopped by the constant north-east and northerly winds, thick weather, and abundance of ice. The neighbouring country was inhabited by *Samoieds*, who had no houses, but only tents made of deer's skins.

Martin
bisher.

The rapid progress made from this time by land through Russia to Persia and India revived the ardour for discovery by sea, and the pens of the most learned and ingenious men in the nation were employed to prove the existence, the practicability, and the great advantages which would result from the discovery of a north-west passage. Amongst others, Martin Frobisher had laboured for fifteen years, but without the means of setting forth an expedition, till at last, in the year 1576, by the assistance of Dudley, earl of Warwick, and a few friends, he was enabled to fit out two small barks, the Gabriel of thirty-five, and the Michael of thirty tons, and a small pinnace of ten tons. On the 11th of July this little squadron came in sight of Friesland, "rising like pinnacles of steeples, and all covered with snow." This Friesland, being in 61° latitude, was probably the southern part of Old Greenland. He entered a strait which now bears his name, in latitude 63° 8′ N., and had communication with the Esquimaux, whom he describes as "like to Tartars, with long black hair, broad faces, and flatte noses." He brought home one of these "strange infideles, whose like was never seene, read, nor heard of before;" and Frobisher had the satisfaction to find himself "highly commended of all men for his greate and notable attempt, but speceally famous for the great hope he brought of the passage to Cathaia."

second
age.

Some of the crew having brought home a stone which "glistend with a bright marquesset of gold," Queen Elizabeth now gave countenance to a second attempt, and added to the expedition "one tall ship of hir majesties, named the Ayde." In this voyage they proceeded to Mount Warwick, on Resolution Island, in latitude 63½° north, whence they sailed on their return home on the 22d of August, having lost only one man by sickness, and another who fell overboard.

third
age.

Though Frobisher brought home neither gold nor silver, but something which had the appearance of both, the queen and her court, pleased in "finding that the matter of the gold ore had appearance, and made show of great riches and profit, and the hope of the passage to Cathaia by this last voyage greatly increased," determined to establish a colony on Meta Incognita; for which purpose fifteen ships were prepared, carrying 100 persons to form the settlement, with whom three of the ships were to remain, and twelve to bring back cargoes of gold ore. The fleet sailed on the 31st of May 1578; part of it entered Frobisher's Strait, and part were driven towards the coast of Greenland. On the 30th of August, the ships having re-assembled off Hatton's Headland, on Resolution Island, and all hands disheartened by the cold and tempestuous weather, they resolved to make sail for England, where they all arrived at different ports about the beginning of October, with the loss, by deaths, of about forty persons.

Pet and
man.

The progress made by land to the eastward induced the Russian Company to fit out two ships, under the command of Pet and Jackman, to make another attempt at a north-east passage. They left Harwich on the 30th of May 1580, reached Wardhuys on the 23d of June, and the coast of Nova Zembla on the 16th of July; passed the Strait of Waygatz, but were obliged to return on account of the ice.

ir
phry
rt.

Sir Humphry Gilbert and his brother obtained from Queen Elizabeth, in 1578, a patent for making western discoveries, by which they established a corporation under the name of "The Colleagues of the Fellowship for the Discoverie of the North-west Passage." In 1583 Sir Humphry set out to take possession of Newfoundland, but the voyage proved most disastrous; and on his return his little bark foundered at sea, when he and all that were in her perished.

Of John
Davis.

In 1585 John Davis was sent out by the merchants of London, for the discovery of the north-west passage. Two barks, the Sunshine and the Moonshine, one of fifty, the other of thirty-five tons, were fitted out for this purpose. On the 6th of August, Davis had proceeded so high up the strait which now bears his name as latitude 60° 40′, and anchored in Exeter Bay, under "a brave mount," to which he gave the name of "Mount Raleigh, the cliffs whereof were as orient as gold." On the 8th of August they returned to the southward, and arrived in Dartmouth on the 30th of September.

His second
voyage.

In 1586 Davis set sail a second time, and coasted the western shore of Greenland up to the latitude of 66° 33′, stood from thence across to the westward, made the land in 66° 19′, and, turning to the southward, along the coast and numerous islands, anchored in a bay on the coast of Labrador, in latitude 56°, and, sailing from thence, arrived in England in the month of October.

His third
voyage.

A third voyage being determined on, Davis sailed from Dartmouth on the 19th of May, made the land on the west coast of Greenland in latitude 64° on the 14th of June, had advanced as high as latitude 67° on the 24th, and, on the 30th, was in latitude 72° 12′. From thence he crossed to the westward in an open sea, but being driven, as he supposed, by a current, found himself, on the 19th, abreast of Mount Raleigh. After this, Davis advanced sixty leagues up the strait he had discovered on the former voyage, now called Cumberland Strait; passed through Lumley's Inlet, the same, it is supposed, which Frobisher had discovered, and known as Frobisher's Strait; and, standing to the south-east, discovered Cape Chidley, and, returning homewards, arrived in England by the middle of September.[1]

Of the voyage of Maldonado in 1588, and of Jan de Fuca in 1592, it is not necessary to say anything; the latter being at best but problematical, and the former altogether spurious.

Voyages of
William
Barentz.

The next attempts we find in chronological order were three voyages for the discovery of a north-east passage, undertaken by the Dutch, in which William Barentz was chief pilot. The first of these was set forth in 1594; proceeded easterly as far as Waygatz, then along the western coast of Nova Zembla as high as latitude 77° 25′; and returned to the Texel on the 16th of September. On the second voyage, the following year, they did not reach Nova Zembla till the 17th of August, when finding it impossible, on account of the great quantity of ice, and "the weather being misty, melancholie, and snowie," they returned to the westward, and arrived in the Maes on the 18th of November.

The third voyage of Barentz is intensely interesting. The ships left the Texel in May, and on the 9th of June, after sailing amongst much ice, they discovered Bear (since called Cherry) Island. Proceeding northerly, they discovered Spitzbergen, along the western coast of which they had advanced, on the 19th, as high as 80° 11′, opposite the point since known as Hakluyt's Headland. Returning to the southward, Barentz made for the coast of Nova Zembla; doubled the northern extremity; then found himself compelled, by the pressure of the ice and bad weather, to seek for refuge in a small bay, which they called Ice Haven; and here they passed "their cold, comfortlesse, darke, and dreadful winter," in about the seventy-sixth parallel of latitude. The ship was wholly wrecked, and the surviving part of the crew, fifteen in number, left this spot the following year in two open boats; and after an exertion of forty days, in which they suffered the greatest fatigue, famine, and cold, and in which Barentz and two others died, they reached Kilduin in Lapland, a distance of a thousand miles and more from the bay in which they had passed the winter.

---

[1] An interesting account of the proceedings of this able and intrepid navigator, by himself, is contained in a very rare and curious little book called *The Worlde's Hydrographical Description*, 1595.

Of George Weymouth.

The merchants of England seem to have lost all hope of a northern passage to the East Indies, till they were once more roused by a supposed piece of information of Captain James Lancaster, that the passage was in the north-west of America, in latitude 62° 30′. Accordingly, in 1602, the Muscovy and Turkey Companies fitted out two fly-boats, the Discovery and Godspeed, the command of which was given to Captain George Weymouth. This voyage, however, proved a complete failure. It is difficult to make out precisely the utmost limit at which it arrived; it was not much beyond Resolution Island in Hudson's Strait; but, to use the words of a subsequent sagacious navigator, Luke Fox, "Davis and Weymouth lighted Hudson into his straits."

Of Hall and Knight.

In 1605, the king of Denmark sent out an expedition of discovery, in which two Englishmen, James Hall and John Knight, were employed. The ships proceeded along the west coast of Greenland, but reached no higher than about latitude 66° 55′; gave the names of Christian's Fiord, and Queen Anne's Cape; traded and quarrelled with the natives; left two malefactors amongst them, and returned to Elsineur. This expedition was followed up by two others in the two following years, neither of which was productive of any discoveries; the first having advanced only to 66° 25′ on the coast of Greenland, and the latter not farther than Cape Farewell.

Of John Knight.

In 1606, the merchants of London sent out the Hopewell, under the directions of John Knight. In latitude 56° 48′, on the coast of Labrador, Knight, with his mate and four others, went on shore, and were supposed to be murdered by the natives, as none of them were ever afterwards heard of. The ship returned home.

The voyages of Henry Hudson.

Henry Hudson made no fewer than four voyages of discovery. The first, in 1607, was along the eastern coast of Greenland, when he reached, in 78° 56′, a higher degree of latitude on that coast than has since been ascended. The second, in 1608, was an attempt to the eastward, where, as in all preceding attempts, he was stopped at Waygatz Strait. Of the third little is known. Its northern limits appear to have been the North Cape on one side, and Newfoundland on the other.

The fourth voyage was fatal to Hudson, but it opened the way to the coast of America in a higher degree of latitude than it had yet been approached. He left the Thames in the Discovery of fifty-five tons, on the 17th of April 1610, and reached the Isle of Godsmercie, in the strait which bears his name, on the 6th of July; on the 2d of August he discovered land, which he named Cape Wolstenholm; and near it, on a cluster of islands, Cape Digges: And here ends Hudson's narrative; for his crew having mutinied, they put Hudson, his son, and seven others, into an open boat, which was never more heard of. The ship returned to England, and, what is most remarkable, the inhuman and atrocious act does not appear to have caused any sensation, nor was any inquiry instituted into the proceedings of the mutineers.

Of Thomas Button.

Two of them, in fact, Abacuk Pricket and Robert Bylot, were employed under Captain (afterwards Sir Thomas) Button, appointed to prosecute the discovery of a north-west passage, in two ships, the Resolution and Discovery. Button followed the tract of Hudson, and succeeded in reaching the coast of America, where he wintered in Nelson's River, in latitude 57° 10′. The following year they stood to the northward, and discovered Southampton Island, as high up as latitude 65°; made some discoveries of islands, and returned to England in the autumn of 1613.

Of James Hall.

In 1612, we find James Hall employed on an expedition up the western coast of Greenland, where he was slain by one of the natives, at Ramel's Point, in latitude 67°. The account of the voyage is written by William Baffin, who was pilot, in which he relates the method of determining the longitude by an observation of the time when the moon came upon the meridian; the first navigator probably who practised this method.

Of C tain Gibb

In 1614, Captain Gibbon was sent out in the Discovery, at the recommendation of Sir Thomas Button. He encountered much ice at the opening of Hudson's Strait, returned to the southward, and was shut up in a bay on the coast of Labrador for five months; and returned without making any progress in north-western discovery. To this bay the ship's company are said to have given, in derision, the name of "Gibbon's his Hole."

Of B ot and B ffin.

In 1615, the Discovery was fitted out a fourth time, and the command of her given to Robert Bylot, who took William Baffin as his mate. They visited Button's Islands, Savage Islands, and Mill Islands, and proceeded along the east coast of Southampton Island to Cape Comfort, in latitude 65°. From thence they returned to the southward, and reached England in the month of September.

In 1616, Bylot and Baffin again set out in the bark Discovery, in search of a north-west passage; and, following their instructions, proceeded up Davis's Strait to Hope Saunderson, the extreme point of Davis's progress, between 72° and 73° of latitude, which they reached as early as the 30th of May. A little to the northward was a group of islands, to which, finding females only, they gave the name of Women's Islands. From hence they stood northerly, between the ice and the land, passing in succession Horn Sound, Wolstenholm's Islands, Whale Sound, Sir Thomas Smith's Sound, in latitude 78°, and at the northern extremity of what has since been called Baffin's Bay; and following the direction of the land, they passed, on the western shore, Alderman Jones's Sound, and lastly, Lancaster Sound; whence the ice compelled them to leave the land, and they therefore shaped their course homewards. This last voyage of Baffin is the most important that had yet been made; and it is quite surprising that the discovery of so many immense openings, which he calls *sounds*, for want of a better word, should not have been followed up, and that not one of them should have been examined until the expedition sent out under that intelligent and enterprising officer Captain Parry.

Of Mu

In 1619, the Danes sent out an expedition under Jens Munck, who penetrated as high up on the coast of America as Chesterfield Inlet, which he named Munck's Winter Harbour; for he wintered in it, and all his people, except two, perished of cold, disease, and famine. Munck and these two survivors with great difficulty fitted out the smaller of the two vessels, and reached Denmark, where they were considered as men risen from the dead. Munck is said to have received the indignity of a blow from the king, on which he took to his bed, and died of a broken heart; but there is an air of romance in the account of this voyage, which makes its authenticity doubtful.

Of Fox

In 1631, Captain Luke Fox, who quaintly calls himself the "North-west Fox," prevailed on some merchants of London to procure from King Charles I. his countenance, and the loan of one of his ships, for attempting the discovery of a north-west passage. Fox was undoubtedly more shrewd and intelligent than all former navigators; and if, when he reached what he calls Fox's Farthest, he had stood across to the westward, the probability is, that he would have got upon the northern coast of America, and succeeded in working his way into the Pacific, by the very route which Parry since pursued.

Of ptain Jan

In the same year the merchants of Bristol fitted out the Maria of seventy tons, the command of which was given to Captain James. In proceeding up Hudson's Strait, somewhere about Resolution Island, he got his ship entangled in the ice; and from that spot to Charlton Island, at the bottom of Hudson's Bay, in latitude 52°, he details a series of disasters which never happened to any navigator before or since. Here he passed the winter, and returned the following year, without making the least progress in discovery.

Captain
niel.

In 1652, the king of Denmark again set forth an expedition under Captain Daniel, to explore the *eastern* coast of Greenland. He stood to the northward of Iceland, but he could not approach the land on account of the ice, though the mountains were visible at least sixty miles. The most northern cape seen was in 65° 30′, to which he gave the name of Cape King Frederick. From this point to Cape Farewell the ice lay between him and the shore, which in no part he could approach within twenty miles; of course, no discovery was made by him.

Wood
Flaws.

After the lapse of more than a century, a paper admitted into the Transactions of the Royal Society of London in 1675 tended to revive the attempt at a north-east passage in England. It contained an account of a Dutch ship, fitted out by a company of merchants in Holland, having passed to the north-eastward of Nova Zembla several hundred leagues, between the parallels of 70° and 80°; and the sea in that direction was found to be perfectly open and free from ice. About the same time it was reported that Spitzbergen had been circumnavigated, and that a Dutch ship had proceeded within one degree of the pole. Upon the strength of these reports, Captain John Wood addressed a memorial to the king, assigning *seven reasons* and *three arguments* for the existence of a north-east passage. Accordingly, two ships were fitted out under Captains Wood and Flaws. They left the Nore in May 1676; on the 22d of June had reached the latitude 75° 79′, and on the 26th got sight of the west coast of Nova Zembla. Three days after this, Wood lost his ship amongst the ice, and after some perils, and the loss of two men in reaching the shore, they were picked up by the other ship, and returned homewards without making the least discovery; when Wood published many peremptory and ill-founded reflections on former navigators, and now found out seven reasons and three arguments *against* the passage to the north-east.

Captain
dleton.

Of the voyages of Knight, Barlow, Vaughan, and Scroggs, from the Hudson's Bay Company's settlements, along the eastern coast of America, little else need be said, than that they did not extend the knowledge of that coast beyond Whale Point; but the observations they made on the strong tide flowing down the Welcome induced a gentleman of the name of Dobbs to press the Board of Admiralty to appropriate a ship of the navy to make discoveries in this quarter. Two ships were accordingly fitted out; the Furnace bomb, and the Discovery pink, commanded by Captain Middleton and Mr William Moor. They left England in 1741, and wintered in Churchill River, in latitude 58° 56′; remained there till the 1st of July; proceeded northerly to the latitude 65° 23′, and entered Wager River, which they examined in an imperfect manner. They then stood to the northward as far as Cape Hope, in latitude 66° 14′, longitude 86° 28′ W.; and, most unaccountably, abandoned all farther search, having seen, or fancied they saw, "a frozen strait" between them and the point round which they had to proceed to the westward. Middleton had been an old servant of the Hudson's Bay Company, who were supposed to be jealous of any discoveries in their neighbourhood, and averse from encouraging them; and he was accused of having taken a bribe from them to defeat the object of the expedition. The lords of the Admiralty refused to approve of his proceedings; and to evince the feeling of the government, an act was passed the very year after his return, offering a reward of L.20,000 to the person or persons, being subjects of his majesty, who should discover a north-west passage through Hudson's Strait to the Pacific. Dobbs, turning these circumstances to the advantage of his favourite project, got up a large subscription, and in 1746 two other vessels were fitted out, and the command of them given to Captain William Moor and Captain Francis Smith.

Of Moor and Smith.

Their first examination was that of the Wager River, which was found to terminate in a broad rapid, beyond which were two unnavigable rivers. They then proceeded northerly, till they came to Captain Middleton's "frozen strait," or opening into Repulse Bay, when a difference of opinion arose amongst the officers, whether they were authorized by their instructions to examine this bay. The fact appears to be, that the officers and men had no taste for the business, and were under no kind of discipline. Instead, therefore, of proceeding, they began to murmur; and although only the 7th of August, they urged the lateness of the season, and wished to return home. After this nothing was done or even attempted; and Repulse Bay remained, till the second voyage of Captain Parry, unexamined.

Of Phipps and Lutwidge.

No farther attempts at either passage appear to have been made by any of the maritime nations for nearly thirty years. But the Honourable Daines Barrington having, in the year 1773, presented to the Royal Society a series of papers on the practicability of approaching the North Pole, the president and council of that society made application to the first lord of the Admiralty (then Lord Sandwich) to send out a ship or ships, to try how far navigation might be practicable towards that quarter. The Racehorse and Carcass bombs were accordingly prepared, and the command given to Captain the Honourable Constantine Phipps and Captain Skiffington Lutwidge. They left the Nore on the 10th of June, passed along the western coast of Spitzbergen, and advanced to latitude 80° 48′, in sight of the Seven Islands; here they were beset in the ice on the 1st of August, and on the 10th, after being forced through it by a north-east wind, they proceeded to the southward, and arrived at the Nore on the 25th of September.

Of Cook and Clerke.

The hopes of a north-west passage were not abandoned by this failure; but it was resolved to make the attempt by a different route to any that had yet been attempted; that is to say, from the Pacific to the Atlantic. Captain Cook was selected for this enterprise, and two ships, the Resolution and Discovery, were fitted out for the purpose, the latter being commanded by Captain Clerke. An amended act was passed for granting the reward of L.20,000 for the discovery of "any northern passage" by sea, between the Atlantic and Pacific Oceans, and also the reward of L.5000 to any ship which should approach the North Pole within one degree. Captain Cook left England in July 1776; entered Behring's Strait on the 9th of August 1779; and on the 17th of August reached latitude 70° 41′ N., and saw the highest point of America, surrounded with ice, and therefore named by him Icy Cape, in latitude 70° 29′, longitude 198° 20′. The main body of the ice drifting down towards the ships, and the weather becoming foggy, they stood to the southward; and as the season was far advanced, Captain Cook determined to pass the winter at the Sandwich Islands, and to renew the attempt at an earlier period the following year. By his death at this place, Captain Clerke became the commanding officer. That he should have failed in reaching as far north as Cook had done, is not at all surprising, after an absence of three years from home, and all hands, as is avowed, "heartily sick of a navigation full of danger." A small vessel had been sent in the year 1776 up Davis's Strait, under Lieutenant Pickersgill, and the same vessel again in 1777, under Lieutenant Young, to render any assistance that might be required, in the event of Captain Cook's reaching Baffin's Bay; but neither of these officers made a progress beyond the 73d degree of latitude.

Admiral Lowe.

In 1786 and 1787, the king of Denmark, at the suggestion of Bishop Egede, sent out an expedition under Captain (afterwards Admiral) Lowenorn, for the purpose of rediscovering the eastern coast of Greenland. This officer persevered for two years, but with no better success than his predecessors. They saw the coast at various points, as high up as 66½°, but could not approach it on account of the ice. No discovery, therefore, of importance resulted from this expedition.

Mr Duncan's voyages.

On the part of England, all further attempts appeared to be abandoned after the failure of Captain Cook. One gentleman, however, Mr Alexander Dalrymple, hydrographer to the Admiralty, considering that three points of the northern coast of America had been clearly established, viz. Icy Cape, by Cook; the north of the Copper Mine River, in 1772, by Hearne; and the mouth of Mackenzie River, by the traveller whose name it bears, in 1789; which three points were supposed to be in or about the 70th parallel of latitude, and that they comprehended within them fully two thirds of the whole of that coast; and combining these discoveries with other circumstances, he was decidedly of opinion that a north-west passage did exist, and that it was practicable. On the strength of this opinion he prevailed on the governor of the Hudson's Bay Company to employ Mr Charles Duncan, a master in the navy, on the discovery. He left England for this purpose in 1790, to join a sloop of the name of the Churchill, then in Hudson's Bay; but he soon discovered that the crew were averse to the intended enterprise, and set up so systematic an opposition to proceeding upon it, that he deemed it prudent to leave them, and to return to England. The governors of the company expressed their regret; and, to prove how much they were in earnest, fitted out a strong ship called the Beaver, and Mr Duncan set out a second time. He wintered in Churchill River, where he remained till the 15th of July, and entered Chesterfield Inlet; but his crew mutinied, encouraged by his first officer, who was a servant of the Hudson's Bay Company; and thus ended his second voyage.

Of the Russian voyages.

We have said nothing of the Russian voyages along the northern coast of Asia. That no one person has performed the whole, either at once or by successive trials, is quite clear; but, with the single exception of one "sacred promontory," called Cape Cevero Vostochnoi, between the Yenisei and the Lena, the whole has been navigated by various persons at different times. In the years between 1734 and 1738, Lieutenants Moroviof, Malgyn, and Skurakof, succeeded in proceeding from Archangel to the Bay of Obe; and in the latter year, Offzin and Koskelef proceeded from that bay to the mouth of the Yenisei. In 1735, Lieutenant Prontshistshef set out in the contrary direction from the Lena, but was stopped by the promontory above mentioned; though some affirm that he passed it, and reached as far as Taimura. From the Lena eastward to the Kowyma the voyage has frequently been performed, and Shaularoff, in 1671, succeeded in reaching the Shelatskoi-noss, but could not double it; and the only instance of its having been passed is that of Deshnef, as far back as the year 1648, who sailed from the Kowyma, through Behring's Strait, to Anadyr.

Of Lieutenant Kotzebue.

The immense distance by sea from St Petersburg to Kamtschatka, and the Russian settlements on the north-west coast of America, would render the discovery of a north-west passage of infinite importance to Russia. Impressed with the magnitude of this importance, an individual of that nation, the Count Romanzoff, fitted out at his own expense a small vessel, named the Rurick, the command of which was given to Lieutenant Kotzebue. She left the Baltic in 1815, passed Cape Horn, and in 1817 entered a deep inlet on the eastern side of Behring's Strait, in which he passed the remaining part of the summer. He found no ice, neither in the strait nor the inlet, and saw nothing to prevent his proceeding up the American coast to Icy Cape but the lateness of the season; and therefore returned to the southward, with the intention of renewing the attempt the following year. An accident, however, which occurred on his second entrance of the strait, though personal only, put an end to the expedition.

Of R and F Buch and F lin.

This voyage of Kotzebue would alone have been sufficient to stimulate England to attempt once more to accomplish the almost only interesting discovery in geography that remains to be made; but other circumstances were reported in the year 1817, which determined the government to fit out two expeditions for northern discovery. A ship from Hamburg, in the summer of that year, made the eastern coast of Greenland, which was supposed to have been shut up with ice for four centuries, in the 70th parallel of latitude, continued along it to the 80th degree, and stood along that parallel to the coast of Spitzbergen. For three years before this, the post-office packets, and other vessels crossing the Atlantic, had fallen in with very unusual quantities of ice floating to the southward. This breaking up of the ice was deemed favourable for the prosecution of northern discovery. For this purpose two separate expeditions were put in preparation. One was intended to proceed by the North Pole, as the nearest route, and, if no interruption from land occurred, probably the most practicable, to Behring's Strait; the other, to attempt a passage by some of the openings leading out of Baffin's Bay. To each were assigned two ships. Those destined for the polar passage were the Dorothea, of 370 tons, commanded by Captain David Buchan, and the Trent, of 250 tons, by Lieutenant John Franklin. Those for the north-west were the Isabella, of 382 tons, commanded by Captain John Ross, and the Alexander, of 252 tons, by Lieutenant William Edward Parry. The polar expedition was rendered abortive by the disabling of the Dorothea in the ice; the other circumnavigated Baffin's Bay, and ascertained that the narrative of that able navigator whose name it bears is substantially true; and that the chart appended to the *Voyage of the North-West Fox* is in fact the chart of Baffin, and wonderfully correct for the time in which it was laid down. Not one, however, of the many great openings which appear in that chart, and were ascertained to exist, was examined; and the only one that was entered was abandoned in a most unaccountable manner, and on grounds which were at once suspected, and subsequently proved, to be utterly without foundation.

Of Pa and L don.

Another expedition was, therefore, immediately fitted out, consisting of two ships, the Hecla bomb and Griper gun-brig, and the command of it given to Lieutenant Parry, Lieutenant Liddon being appointed to that of the Griper. They dropped down the river on the 4th of May 1819; saw Cape Farewell on the 15th of June; and by the 30th of July had succeeded in crossing the ice of Baffin's Bay, and reaching the opening of Sir James Lancaster's Sound, just one month earlier than in the preceding year. To the examination of this sound Mr Parry was particularly directed by his instructions. In proceeding along it to the westward, he met with little obstruction from the ice (though he was evidently navigating through an archipelago of islands, where it usually most abounds) until he came to the western extremity of what he calls Melville Island, the last that was visible on the northern side of the strait or passage through which he had proceeded. Beyond this he struggled in vain, till the 20th of September, to get to the westward, when the severity of the weather made it prudent to look out for a secure spot to pass the winter; and, after cutting a canal through the ice upwards of two miles in length, tracked the two ships into Winter Harbour, the crews "hailing the event with three loud and hearty cheers." The following year, when released from their icy prison, every effort was again made to pass the western extremity of Melville Island, but in vain; and, after many fruitless attempts, the ships returned to the eastward, and reached England in safety, bringing back every man who had embarked on the expedition, with the exception of one, who carried out with him an incurable complaint.

The farthest point reached by Lieutenant, now Captain, Parry in the Polar Sea, was latitude 74. 26. 25. north, and longitude 113. 46. 43. west; a point of western longitude which, by an amended act of parliament, dividing the sum of L.20.000 into a graduated scale, entitled the discoverers to L.5000.

arry Lyon.

On their return to England, there was not an officer or man in the whole expedition that was not satisfied with the practicability of a western passage from the Atlantic to the Pacific, though in some other line of direction, either to the northward or the southward of the extensive group of islands amongst which they had been navigating. The lords of the Admiralty appear to have entertained the same feelings, and accordingly gave directions for two bombs, the Fury and the Hecla, to be prepared for the prosecution of the discovery. To Captain Parry was given, as was justly due, the command of the expedition, and to Captain Lyon that of the Hecla. They left England in May 1821, and on the 2d of August arrived in the channel formed between Southampton Island and the coast of America; passed the *Frozen Strait* of Middleton, and unconsciously entered Repulse Bay, "wherein was not a piece of ice to be seen." They found it entirely surrounded by land. Proceeding to the northward along the coast of America, they examined several inlets, all of which terminated at short distances from their entrance. The arrival of the 1st of October gave sufficient indications of the necessity of finding some place to pass the winter in; and after much research, to a small island selected for that purpose, Parry gave the name of *Winter Island*. Its latitude was observed to be 66¼°, the lowest temperature, during the winter, was — 40°.

On the 2d of July they left Winter Island, proceeded up Fox's Channel, in which, from the strength of the current, and the floating masses of ice, both ships had a narrow escape from being *nipped*, that is, *crushed* between the huge hummocks. At length they reached the latitude of 67° 18′, where they found a considerable opening in the land of America, out of which a strong current was observed to set into the sea. It turned out, on examination, to be the mouth of a fresh-water river. Proceeding still northerly along the coast of America, they came to a strait which had been previously indicated by a party of Esquimaux at Winter Island, and which one of the women, of a very superior cast, had marked down on a chart, with extraordinary correctness. Near it was the island of Igloolik, where (the 30th of October having arrived) they resolved to take up their second winter quarters. Its latitude was 69⅓°, the lowest temperature 45° below zero. That horrible disease, the scurvy, having, in the following spring, made its appearance, both amongst the officers and the crews, which, however, yielded to the universal specific, lemon-juice, Captain Parry, by the advice of the surgeons, deemed it expedient, as soon as the ships could be liberated, to make the best of his way home, where he arrived on the 18th of October, having lost, in the course of the voyage, and the two winters he was shut up in the ice, five of his crew, three by sickness, one of previous disease, and one killed, out of the two ships' companies amounting to 118 men.

The result of this voyage forms a valuable and important addition to our geographical knowledge. The strait near which they wintered was named by Parry the *Fury and Hecla Strait*. The north-eastern termination of the continent of America was for the first time ascertained to be the southern point of land forming its entrance, and is in latitude 69° 41′ north, longitude 82° 35′ west. The narrowest part of the strait is about two miles across; its length about sixty geographical miles, where it joins Prince Regent's Inlet. It is through this strait that the waters of the Polar Sea are poured, in a perpetual current, into the Welcome and Fox's Channel, carrying with them those fields and hummocks of ice that accumulate in the *Frozen Strait*, and amongst the narrows between the islands that occur from this point down to Hudson's Bay. The strait itself is so choked with ice, adhering to its two shores, as to render it unfit for navigable purposes, otherwise it would be the nearest and most direct line to pursue to get into the Polar Sea through the lower portion of Prince Regent's Inlet.

A third attempt was made in the Hecla and Fury in the years 1824–1825, the least successful of all. In this voyage Parry entered Lancaster Sound, and, instead of proceeding westerly, as he had before done, towards Melville Island, he deemed it expedient to strike off to the southward, down Prince Regent's Inlet, on the supposition, that having reached the current which he had previously ascertained to pass through the Fury and Hecla Strait, he would find himself in the direct line of the passage that would bring him to Icy Cape. It was, however, with much difficulty he was enabled to reach Port Bowen on the eastern shore of the inlet, on account of the vast masses of ice that almost filled up this strait or inlet; and it was then so late in the season that he resolved to winter in this port. On the 20th of July following, the ships were released from their winter quarters by the disruption of the ice; but such was the pressure of the vast masses by which they soon found themselves surrounded, that both ships were driven on shore, and the Fury was finally wrecked. Parry was therefore under the necessity of taking on board the crew of the Fury, and as much of her provisions as he could stow, and of making the best of his way to England.

Of Parry and Ross.

Parry was not in the least disconcerted by the unsuccessful issue of the last voyage. He offered his services on a new plan of discovery, which indeed had already been proposed by Sir John Franklin. This was to proceed to the northern extremity of Spitzbergen, and from thence, with boats, to make the attempt to reach the North Pole. These northern voyages had always been popular from the earliest periods of British navigation. The president and council of the Royal Society addressed a letter to Lord Melville, signifying their approval of Parry's proposal, and stating their opinion, that such an enterprise could not fail to afford many valuable scientific results, and to settle points of philosophical inquiry. The Hecla was again put in commission for this service. She left the Nore the beginning of April 1827, and on the 14th of May was abreast of Hakluyt's Headland, and in June was anchored in a bay in latitude 79° 55′ north, longitude 16° 54′ east. From thence Parry proceeded in two sledge-boats, which he named the Enterprise and Endeavour; Parry in the one, and Lieutenant (now Captain) Ross in the other. At first they had to contend with loose and rugged ice, amongst which were pools of water; they then came to floe or field-ice, in places rugged, and sometimes covered with snow. Over these the boats were to be hauled, which proved a most severe and laborious task, the result of which was a progress of four or five miles a day due north, seldom more. But the most mortifying circumstance of all was, that when they thought they had advanced some ten or twelve miles to the northward, they found that they had retrograded as many miles to the southward, the floe on which they were exerting themselves having been carried by the current in that direction. In this way they struggled for thirty-five days, when, having expended half their provisions, and the season approaching to its termination, it was resolved they should return to the ship, the farthest point that they had reached being only 82° 45′ north, longitude 19° 25′ east.

It has been observed, that this unsuccessful attempt "is of so bold and daring a character, that it must stand as a record to the latest posterity, of the patient, persevering, energetic, and undaunted conduct which British seamen are capable of displaying in the most difficult, discouraging, and dangerous circumstances, when under the command of prudent and intelligent officers, in whom they have entire confidence. On their return they met with open water to a considerable extent, and they reached the Hecla in sixty-one days from the time they had left her. If any future attempt to reach the pole be undertaken, it should not be made by boats, which are at the mercy of every current, and of every floe of ice with which they may come in contact; but in a small sailing vessel, that can take advantage of the open water, which every breeze from the northward affords to a vast extent. The distance is so short, that the success of an expedition of this kind is far from improbable.

Of Ross.

Of Captain (now Sir John) Ross's expedition little need be said. It was a bold but inconsiderate undertaking, and every soul who embarked on it must have perished, but for the ample supplies they received from the Fury, or rather from the provisions and stores which, by the providence of Captain Parry, he had ordered to be carefully stored up on the beach; for the ship herself had entirely disappeared. He proceeded down Regent's Inlet as far as he could in his little ship, the Victory; placed her amongst the ice clinging to the shore, and after two winters left her there; and, in returning to the northward, by great good luck fell in with a whaling-ship, which took them all on board, and brought them home. Captain James Ross, by his indefatigable exertions, collected some geographical information, and proceeded along the eastern coast of the land which Sir John Ross has named Boothia, out of compliment to his generous friend Booth, who bore the expenses of the expedition; and in this journey Ross came to the spot on which, he informs us, the magnetic pole was then situated.

Expeditions of Beechey, Franklin, Richardson, Simpson, Back, &c.

Captain Beechey was employed on a surveying expedition along the western coast of North America, and when he had reached Behring's Strait he despatched his master, in the long-boat, round Icy Cape, to endeavour to fall in with Sir John Franklin, who was proceeding westerly from Mackenzie's River towards Icy Cape. These two officers, uncertain of their respective situations, returned each the way they had come, when about one hundred and twenty miles distant from each other. At the same time Dr Richardson had proceeded easterly and surveyed the American coast as far as Hearne's River, Franklin on a previous expedition having surveyed from thence to Cape Turnagain. The interval between the point reached by Beechey's master and that by Franklin on the second journey was, in the summer of 1837, accurately surveyed by Mr Simpson and the servants of the Hudson's Bay Company, who, with a zeal and spirit that cannot be too strongly approved, are in the present summer of 1838 engaged in completing that part between Cape Turnagain and the bottom of Regent's Inlet, which Captain Back was sent by land to complete, but was too late in reaching the coast for the party to undertake it. Captain Back in the year 1837 was sent, in the Terror, to land at Wager River or Repulse Bay, with the view of accomplishing what the Hudson's Bay servants are in the present year engaged upon; but his attempt was a complete failure, owing to the ship being immoveably fixed in the ice which adhered to the shore of Southampton Island.

Probability of a passage, from the information obtained.

The sketch here given of the various attempts which have been made for the discovery of a north-west, a north-east, and polar passage, is purely *historical*. The results have been uniformly unsuccessful; but though they have failed in the main object, it must not be concluded that they have been useless. On the contrary, they have been the means of accumulating a stock of information of the highest importance in almost every department of science, so as to entitle those who, at the expense of every personal comfort, embarked in them, to the gratitude of mankind. From the present state of our knowledge thus acquired, a very probable conjecture may now be formed of the practicability, or otherwise, of a navigation through some part of the Polar Sea.

In the first place, it has been distinctly ascertained that human beings can winter with impunity to their health in the highest possible degree of cold which can exist in any part of the earth's surface; for there is every reason short of actual proof to believe, that the temperature of the atmosphere on the pole itself is not lower than, perhaps not so low as, in the parallel of 75°, where Parry wintered; the spirit in the thermometer having there descended to 55° below zero. So little, indeed, is a high parallel of latitude the sole cause of a decreased temperature, that, in 65° north, ten degrees less than Parry's winter-quarters, Lieutenant Franklin had the spirit in the tube down to 57°, two degrees lower than Parry. This officer, therefore, left England with the impression that he should experience no injury, nor much inconvenience, from passing a second winter in the Polar Sea, if it should be found necessary.

In the second place, it has now been ascertained in what situations it would be a waste of time to look for a passage, and where the only remaining points are deserving of examination. That a communication, if not a practicable passage, does exist between the Atlantic and the Pacific Oceans, through the medium of the Polar Sea, very little doubt can remain. The constant current which the old navigators Button, Fox, Middleton, and since their time Parry, Lyon, and Back, found setting down the Welcome, and which also, in a less degree, prevails in Baffin's Bay and Davis's Strait, together with the current which as constantly sets up Behring's Strait, as appears from the journal of Cook, Clerke, Glottof, and Kotzebue, testifies to this position. The fact of this circumvolving current, which we have no doubt contributes to those permanent movements everywhere existing in the great oceans, has been called in question, because, forsooth, Sir John Ross found it running as much one way as the other in Baffin's Bay. Sir John Ross had no further knowledge of currents than of those which are generally found to agitate the surface of the sea, and which are known to change with every wind. Superficial currents, however, are not here meant, but the uniform motion of that great body of water, which, in spite both of winds and superficial currents, and in the teeth of both, carry icebergs many hundred feet immersed below the surface, and bear them along the coast of America, in direct opposition to the strongest and most extensive current that we know of, the Gulf Stream. How happens it, then, it may be asked, that none of these icebergs, so very commonly met with in the Atlantic, ever come across to the coast of Norway or Denmark, Scotland or Ireland, with the spread of the said Gulf Stream, after it reaches the banks of Newfoundland, and carries with it so many other matters, floating on the surface, to these coasts? Or why do all the bottles which have been launched in Davis's Strait leave the direction taken by the icebergs, and turn up on some of the above-mentioned coasts? Clearly, because there is a body of water acting on those parts of the icebergs under the surface (and which are at least thirty times the magnitude of the parts above the surface) in a contrary direction to that which is in motion above. The fact is so obvious as not to require another word on the subject. It is the icebergs *only* that are subject to this law. The field-ice, which is influenced and drifted about according to the winds and the currents on the surface, gives no indication of the direction in which the great body of water is moved.

In the same manner, we may be satisfied of the constant rush of water from the Pacific, through Behring's Strait, into the Polar Sea, to supply the constant stream which flows down the Welcome into Hudson's Bay. It is this current which, according to the observations of Kotzebue and the naturalist Chamisso, brings the great quantity of drift-wood found in Behring's Strait and Kotzebue's Inlet. It is the same current by which, on the same authority, we are told, the icebergs and fields of ice, which are formed and break up in the sea of Kamtschatka, "do not drift, as in the Atlantic, to the south, but into the strait to the north;" and the strength of this set of the sea is stated to be from two and a half to three miles an hour, and that even in the teeth of a strong northerly wind. The conclusion drawn by M. Kotzebue is this, "that the constant north-east direction of the current of Behring's Strait proves that the water meets with no opposition, and, consequently, that a passage must exist (to the Atlantic), though perhaps not adapted to navigation. Observations have long been made that the current in Baffin's Bay runs to the south; and thus no doubt can remain that the mass of water which flows into Behring's Strait takes its course round the northern shore of America, and returns through Baffin's Bay into the ocean. But we have still more direct and positive information. Two Russian ships doubled the Icy Cape in 1821, and proceeded some forty or fifty miles beyond the point reached by Captain Cook; and such was the strength of the current *to the eastward*, that it was with the utmost difficulty they could stem it on their return, which a want of provisions, and of every requisite to pass the winter or encounter ice, compelled them to do; but they had no doubt whatever of a practicable passage.

An idea has heedlessly been started, that the superficial current in Baffin's Bay, and that which descends along the coast of Labrador, may be owing to the melting of the ice in summer; but if so, why does not the summer current at least descend through Behring's Strait instead of perpetually ascending it? But the supposition is altogether without foundation; for the quantity of ice destroyed *above* the surface will be replaced by very nearly the same quantity rising from *below* the surface; and, therefore, the water produced by the melting of the ice will merely supply the place of the latter, and not raise the surface of the sea above its usual level, nor produce any current. Be it observed, too, that in the arctic regions little or no increase of the ice is occasioned by the fall of rain or snow, which are of trifling amount.

Another objection, equally frivolous, was taken against a communication of the waters of Hudson's Bay and Behring's Strait, on the ground that the continent of Asia overlapped and was united to America, making Behring's Strait to terminate in a great bay. *That* question, however, has been set at rest for ever, even with those who were disposed to doubt of the voyage of Deschreff. The Russian government has recently employed several men of science to determine points of doubtful position on the northern coast of Siberia. In February 1821, Baron Wrangel, a distinguished officer in their service, left his head-quarters on the Nishey Kolyma, to determine, by astronomical observation, the position of Shelatskoi-noss, or the north-east cape of Asia, which was found to be in latitude 70° 5′ north, considerably lower than it is usually placed on the maps. He then proceeded over the ice directly north for eighty miles, without perceiving any other object than a boundless field of ice. The supposed continuation, therefore, of Asia to the eastward, may be considered as an idle speculation.

But the perpetual current from Behring's Strait has been traced along the whole extent of the northern coast of America into Hudson's Bay (with the exception of some 200 miles not yet examined), by Beechey, Franklin, Richardson, Back, and the Hudson's Bay Company, and so distinctly, as not to leave a doubt on the subject; and Parry found it discharging itself impetuously into Fox's Channel, and down the Welcome through the Strait of the Hecla and Fury. These facts, then, being established, it may be assumed that a water communication does exist between the Atlantic and Pacific; and that, from the low latitude of the coast of America, may be inferred the probability that this communication is a navigable one. The question, then, is narrowed to the direction in which it is most probable a passage will be found? The north-eastern route may be given up, were it only for the great distance (just one half of the whole circumference of the Polar Sea) that it would be necessary to navigate, more or less, amongst ice.

Probable direction of the passage.

The tract pursued by Parry on his first voyage through Barrow's Strait, and amongst the islands, must obviously be given up as hopeless. The prevailing north-westerly winds wedge in amongst the islands such a mass of ice, which never melts, as to render all attempts to penetrate it at the western opening of the funnel impracticable; but beyond this ice, Captain Parry had no doubt there was an open sea, as it was observed, that, whenever the wind came to the eastward, the whole body of the ice kept moving to the westward for several days together. And this open sea is probably not inaccessible from some other quarter. Indeed we now know, that from the concurring reports of those who have examined the line of coast which terminates America, and from Captain James Ross when on the western shore of Boothia, that neither land nor ice was visible to the northward in the first case, nor to the westward in the second. It is clear, then, that to effect a passage to Behring's Strait, the route should be through Lancaster Sound (always free from ice), along Barrow's Strait, to the first opening beyond that of Regent's Inlet, proceeding in a slanting direction to the south-west till the coast of America be in sight, and then westerly to Icy Cape. It is much to be wished that a trial were made of this passage. The attempts hitherto made have taught us that straits, and islands, and shores, should be avoided, as the ice is generally found to block up the first, and by grounding to adhere to the others, and render navigation impracticable. Parry, and Lyon, and Back found that to be the case in the straits through which they in vain attempted to pass; whilst, as all the Greenland fishermen know, there is little obstruction in the field-ice of the open sea, which breaks up and is scattered in all directions by moderate breezes of wind.

Probable mean temperature of the pole.

Sir David Brewster, in an ingenious and interesting paper on the Mean Temperature of the Globe, has shown, in a satisfactory manner, by comparing the results of the late expeditions with those he had drawn from a preconceived theory, "that the mean temperature of the north pole of the globe will be about 11°," which, he says, is "incomparably warmer than the regions in which Captain Parry spent the winter." The mean annual temperature of this spot, according to a series of accurate observations for twelve months, was actually 1° 33′; and on shore could not have been more than 1° below zero.

Coast of the Polar Sea inhabited.

In fact, the whole surrounding coast of the North Polar Sea is inhabited; the European part with Laplanders and Finns; the Asiatic shores with Ostiacks, Samoieds, Yuckagires, Tchutskies, and Koriacks, who derive their subsistence from the rein-deer and dried fish. The Tchutskoi bordering on Behring's Strait are a superior kind of Esquimaux, and are no doubt the same race which extend along the northern coast of America, the shores and islands of Baffin's Bay, Davis's and Hudson's Straits, and the coast of Labrador; and as high up on the coast of Old Greenland as latitude 78°, the highest habitable spot, in all probability, on the face of the globe. All these people, distantly as they are removed from each other, speak the same language, wear the same dress, subsist in the same manner, and in all their habits and appearance are precisely the same people. Spitzbergen has no permanent inhabitants; but English, Dutch, Danes, and Russians, have frequently wintered there; and, even as high as 80° north, many hundreds, some say thousands, of graves are met with in two or three particular spots where it was usual with the Dutch and other nations to extract the oil from the whale and other marine animals furnishing blubber. On Nova Zembla, the body of which is five or six degrees lower in latitude, no inhabitants are found, nor, with the exception of Barentz and his associates, have any been known to pass the winter even in the more southerly parts. Such, indeed, is the difference of climate on the same parallels, that whilst on the southern part of Nova Zembla, in latitude 69°, not a shrub is to be found, at Altengoord, in Norway, in latitude 70°, trees grow to a considerable size. Old Greenland, and the islands on the western shore of Baffin's Bay, of Davis's Strait, and of Hudson's Bay, down to the 55th degree of latitude, are barren of trees and shrubs; whilst on the western side of America, as high up as the 60th and even 65th degree, the firs and birch grow to a considerable size. Even in the short distance which separates America from Asia across Behring's Strait, Kotzebue, in passing from the former to the latter, experienced a change like that of summer and winter; in the former all was verdure, in the latter a complete surface of ice and snow. On the south side of Melville Island, in 75° of latitude, the moment that the snow had departed, the ground was enamelled with a variety of brilliant flowers.

Animals of the northern regions.

Nor are these dreary regions entirely destitute of animated nature. Rein-deer are met with on the northernmost part of Spitzbergen. The polar bear, the wolf, the arctic fox, the polar hare, the ermine, the lemming or Hudson's Bay mouse, the musk-bull, and the rein-deer, were all caught on Melville Island, the first six being perpetual residents, the two last migratory. Grouse, ptarmigan, plover, and a great variety of water-fowl, frequent in vast numbers the straits and islands of the Arctic Seas. The following picture, drawn by the naturalist who accompanied Kotzebue, is correct and interesting. "As, on the one hand, in proportion as you advance farther on the land towards the north, the woods become less lofty, the vegetation gradually decreases, animals become scarcer, and lastly (as on Nova Zembla), the rein-deer and the *glires* vanish with the last plants, and only birds of prey prowl about the icy streams for their food; so, on the other hand, the sea becomes more and more peopled. The *algæ*, gigantic species of *tang*, form inundated woods round the rocky coasts, such as are not met with in the torrid zone. But the waters swarm with animal life,—the *medusæ* and *zoophytes*, *molluscæ* and *crustaceæ*, innumerable species of fish, in incredibly crowded shoals; the gigantic swimming *mammalia*, whales, physeters, dolphins, morse, and seals, fill the sea and its shores, and countless flights of water-fowl rock themselves on the bosom of the ocean, and in the twilight resemble floating islands."

SOUTH POLAR SEA.

Confined knowledge of the South Polar Sea.

Of the South Polar Sea little or nothing may be said to be known. Captain Cook, in the years 1773 and 1774, crossed the antarctic circle in *five* places only; in longitude 39½° east, where he advanced to latitude 67½°, and met with fields and detached pieces of ice; in longitudes 101° and 110° west, between which he proceeded to latitude 71° 10′ south, the farthest progress made by him towards the south pole, where he was stopped, or at least deemed it prudent to return, on account of the fields and mountains of ice which were scattered over the surface of the sea; and in longitudes 136° and 148° west, between which he descended to latitude 68°, and saw many floating ice islands. There are, therefore, still remaining about 340 degrees of longitude in which the antarctic circle has not been crossed, and full half the circumference of the globe which has not been visited lower to the southward than the parallel of 60° south latitude.

Mr Weddell, a master in the navy, proceeded some three degrees farther south than Cook; and since that, two ships of Mr Enderby discovered a long tract of land, the extent of which they did not determine. It is understood this spirited gentleman either has or is about to send out other ships to prosecute at the same time the whale-fishery and maritime discovery.

There was little doubt of the existence of high land in the South Polar Sea, though Cook discovered none beyond the Southern Thule, or Sandwich Land, on the parallel of 60°. Without high precipitous land, those large icebergs which he met with floating amongst the fields of ice could not have been formed; the *hummocks* of ice, occasioned by the agitation of the sea and the meeting of the *fields* or *flaws* in opposite directions, seldom rise to the height of twelve or fifteen feet above the surface. The Russians, indeed, on a recent voyage of discovery, are said to have fallen in with many islands about the seventieth parallel of latitude: they also circumnavigated the Sandwich Land, which was left undetermined by Cook, and conjectured that it might be a part of the great southern continent, which occupied so much of the attention of the geographers and philosophers of the last century. This idea was renewed by the recent discovery of a very considerable extent of land to the southward of Cape Horn, in latitude 63°, and seen extending from longitude 55° to 65° west. As the eastern extremity had not been seen, and the winding of the coast was to the north-east, it was conjectured that it might unite with the Southern Thule of Cook, and form the long-sought-for southern continent. It is said, however, that the Russians have also circumnavigated this land, and that it is composed of a great cluster of islands.

The land in question has been called South Shetland, but it is no new discovery. In the account of the voyage of *the Five Ships of Rotterdam*, under the command of Jacob Mahu and Simon de Cordes, to the South Seas, in the year 1599, it is stated, that, on approaching the Strait of Magelhaens, the yacht, commanded by Dirk Gherritz, was separated from all the other ships, and was carried by tempestuous weather to the south of the strait, to 64° south latitude, where they discovered a high country, with mountains which were covered with snow, like the land of Norway. This land of Gherritz was marked on some of the old charts, but discontinued on the more modern ones, from the uncertainty of its position with regard to longitude. There can be no doubt of its identity with the modern South Shetland. It answered to the description of the mountains of Norway, covered with snow, and is wholly barren, having neither tree nor shrub of any kind. It is unnecessary to say that it is uninhabited, there being no such people in the southern hemisphere as the Esquimaux; and it may be remarked, that no human beings are found in the Southern Ocean below the fifty-fifth parallel of latitude, and none beyond the fiftieth, except on Patagonia and Tierra del Fuego. On the shores, the seals and sea-horses, which had remained from the creation undisturbed, were so numerous, that, on the first notice of the rediscovery, a whole fleet of vessels from England and North America crowded thither on speculation; but the loss of several, from tempestuous weather and a dangerous navigation, and the destruction and alarm of the objects of their cupidity, will probably cause it, for some time at least, to remain as much a land of desolation as it had been before. (M.)

POLARISATION OF LIGHT.[1]

Until a very few years since, the greater number of natural philosophers, and almost all mathematical opticians, were agreed in considering the rays of light as composed of extremely minute molecules, darted, in every possible direction, by a luminous body, with very great velocities. The form of these molecules remained undetermined; but as it was inferred from some observations, made long ago, that certain rays had not the same properties in every part of their circumference, it was natural to compare them to little magnets, and to suppose them possessed of poles. Hence the appellation of a *polarised ray* was applied to every ray of light so modified as to exhibit the polar properties of its molecules. We shall begin this article by describing the different methods that have been discovered for obtaining polarised rays.

SECT. I.—OF DOUBLE REFRACTION, CONSIDERED AS A MODE OF POLARISING LIGHT.[2]

Supposing a pencil of *natural light*, that is to say, of light coming directly from a luminous body, without having undergone any change by refraction or by reflection, to fall upon a crystal of carbonate of lime, perpendicularly to one of its surfaces, either natural or artificial: This pencil will in general undergo a bifurcation as it enters the crystal; one half of the incident light continuing its course in a right line, according to the ordinary laws of refraction, and the other exhibiting a very remarkable phenomenon, and assuming an oblique direction, notwithstanding its original perpendicularity. The former half is called the *ordinary pencil* or ray, the latter the *extraordinary pencil* or ray. The plane passing through these two pencils must obviously be perpendicular to the surface of the crystal: this plane is of great importance in the phenomena of polarisation, and it is denominated the *principal section* of the crystal.

According to this definition, it appears that every ray of light, at each point of incidence on a given crystal, will have a principal section corresponding to it; and we have only to observe, that all these sections will be parallel to each other. In a rhomboid of Iceland spar, the principal section cuts the natural faces of the crystal in a line parallel to the diagonal joining the obtuse angles of the parallelogram, and dividing it into two equal parts.

Now, the *ordinary* and *extraordinary* rays both *acquire* within the crystal *new properties*, not inherent in the direct light. In order to show this, it will be sufficient to remark what happens to these rays when they fall on a second crystal which has the properties of double refraction; and, first, with respect to the ordinary ray, which has preserved its rectilinear direction without deviation.

If the principal section of the second crystal *is parallel* to the principal section of the first, the ray will undergo no double refraction in the second, but will continue its course without any subdivision. But if the principal sections of the two crystals are perpendicular to each other, the ray which was *ordinarily* refracted in the *first* crystal, will become an *extraordinary* ray in the *second*, and will be refracted obliquely when its incidence is perpendicular. But when the principal sections are neither perpendicular nor parallel to each other, this same ordinary ray will be subdivided in the second crystal, but its portions will be of different intensities, excepting when the sections form an angle of 45° with each other.

The extraordinary pencil exhibits phenomena of a similar nature. It remains an extraordinary pencil in every crystal of which the principal section is parallel to that of the crystal which has transmitted it, and becomes an ordinary pencil when the principal sections are at right angles to each other. It is subdivided into two pencils of equal intensity if the two sections make an angle of 45° with each other, and, in every other position, into two pencils of unequal intensities.

It is extremely easy to verify these propositions by experiment. We place on a horizontal table a piece of black paper, and draw two very fine lines at right angles to each other, with a white spot of a certain magnitude at their intersection; and we lay on the paper a rhomboid of calcareous spar, and with our eye immediately above the spot we see two images of it, situated in a line parallel to the shorter diagonal of the upper face of the rhomboid. One of these images is seen in the true place of the spot, as is easily ascertained by two lines which cross in it, and of which the portions not covered by the crystal point at it; these rays have therefore undergone no deviation, and have been ordinarily refracted. The other rays have been bent, since they do not pass through the true place of the spot, and therefore afford the extraordinary image.

We now place a second crystal on the first, in such a manner that the shorter diagonals of the faces in contact may be parallel; and we still find only two images of the white spot, but they are more remote from each other. The one retains its natural situation; whence it follows, that the rays which afford it are no more deflected from their course in the second crystal than they are in the first, and that they have always remained ordinary rays. With regard to the second image, since it is more remote from the true place of the object than when seen through the first crystal only, it is obvious that the rays, which have already been extraordinarily refracted in the lower rhomboid, have undergone the same kind of refraction in passing through the upper.

If we only turn the upper rhomboid round the vertical line, so as to remove its principal section from its parallel position, each of the two images will be subdivided into two others. The new images will at first be very weak; but their intensity will augment by degrees at the expense of the original images, in proportion as the angle formed by the two sections becomes greater; and at last, when it is a right angle, the two primitive images will have disappeared, and the new images alone will remain. One of them will be at a distance from the true place of the spot, in the direction of the shorter diagonal of the upper rhomboid, about equal to the result of the double refraction of the second crystal if it were separate from the first. This image is therefore formed by rays which have been refracted ordinarily in the first crystal, and extraordinarily in the second. And it will be equally manifest that the other image is derived, on the contrary, from rays refracted at first extraordinarily, and then ordinarily, in the respective crystals.[3]

As it is difficult to procure very thick rhomboids of carbonate of lime that are quite transparent, the same experiments may be performed by means of two prisms, cut out of doubly refracting crystals, and rendered achromatic by combining them with prisms of common glass placed with their bases in opposite directions. Through two such achromatic prisms placed on each other, the image of a candle appears quadruple or double, according to the relative positions of the principal sections. We thus see very distinctly that the images which disappear are not confounded with the other two, but that they become fainter gradually, whilst the others increase in intensity by the same degrees.

---

[1] This article was written by M. Arago of the French Institute, and obligingly translated by his friend the late Dr Thomas Young, for the *Supplement* to the previous editions of this work. Some additions were, with M. Arago's permission, made by the translator.

[2] See the article Optics, vol. xvi. p. 461.

[3] *Ibid.* p. 461, 462.

It appears, then, first, that the direct light is *always divided* into two pencils in its passage through the natural faces of a crystal of carbonate of lime; and, on the contrary, that the light of which either of the two pencils is composed, when submitted to the action of such a crystal, in *some particular positions* of the principal section, *is not divided*, and gives but a single pencil.

Secondly, the two images furnished by the direct light have always an *equal degree* of brightness; but the light of the ordinary or extraordinary pencils, when it undergoes a further double refraction, gives almost always images of unequal intensities.

Hence it follows, that in the act of double refraction this last light has received some new properties, by which it may always be distinguished from natural light. But are these properties necessarily of such a nature as to be inexplicable without supposing the elementary molecules of the rays to possess certain poles? This is a question which we are now to examine.

We will suppose that a rhomboid of carbonate of lime is placed horizontally; that the incident light falls perpendicularly on its upper surface, and that the principal section, which will be vertical, is in the plane of the meridian, or that it runs north and south; observing, however, that these directions are only chosen to facilitate our comprehension of the facts.

The ordinary pencil afforded by this crystal when it is submitted to the action of a new rhomboid similarly placed, that is to say, having also its principal section in the plane of the meridian, passes through it, as we have seen, without lateral refraction, and continues its course in a right line, remaining as an ordinary ray.

But when the principal section of the second crystal, being still vertical, is directed from east to west, the ordinary ray, transmitted by the first crystal, will be refracted laterally in it, although it falls perpendicularly on the surface, and will become an extraordinary ray.

In the first case, the principal section of the second rhomboid intersected the ray, or the luminous molecules supposed to compose it, from north to south; in the second, these molecules were intersected from east to west. It may be remarked, that this is the only circumstance in which the cases differ from each other, the ray falling in both cases on the same point of the crystal, and in the same angular direction. It must therefore be concluded, that in the ray of light, or in the elements of which it is formed, the north and south sides must have different properties from those of the east and west.

When we analyse the extraordinary pencil with the second crystal, if the principal section intersects this pencil from north to south, it undergoes the extraordinary refraction, but it follows the ordinary course when this same plane intersects it from east to west, which is exactly the contrary of what occurs with the ordinary pencil. The north and south sides of this pencil have therefore the properties of the east and west sides of the extraordinary pencil, and the reverse; nor is there any other difference between the pencils; the sides possessed of similar properties are only differently directed, so that if we could cause an extraordinary ray transmitted by any crystal to make a quarter of a revolution on itself, it would be impossible to distinguish it from the ordinary ray that has been separated from it.

When natural philosophers say of a loadstone or a magnet that it has poles, they merely understand by this expression that certain points about the circumference of the magnet possess properties which do not belong, either at all, or in the same degree, to the other parts of the circumference. It was then equally correct to say of the ordinary and extraordinary rays derived from the subdivision of natural light in the crystals of carbonate of lime, that they had *poles*, or were *polarised*. It is only necessary to remark, in order to avoid extending the analogy between the rays of light and the magnet beyond its proper bounds, that for every element of the ray, the sides or poles diametrically opposite to each other, that is, in the position here supposed for illustration, the north and south poles of the ordinary ray, appear both to possess exactly the same properties; and it is at the angular distance of 90° from these points, that is, on a perpendicular to the line that joins them, that we find in the same ray poles possessed of different properties; and if we compare with each other the two pencils transmitted by a given crystal, the poles possessed of the same properties will be situated in directions perpendicular to each other.

Let us once more consider the two rays transmitted by a crystal of which the principal section is supposed to be in the plane of the meridian. There is no reason whatever for assigning the denomination of poles to the north and south sides of the ordinary ray rather than to the east and west; but as it is necessary to make some distinction, it has been generally agreed to apply the name of poles to the north and south sides. Hence it has been usual to say, that the *ordinary ray* is polarised in the *plane of the principal section;* which is as much as to say that the different elements of the ray have the faces, which we have called poles, situated in that plane. The *extraordinary ray is polarised perpendicularly to the principal section;* its poles are situated perpendicularly to that plane, since it becomes perfectly similar to the ordinary ray when it is made to describe a fourth of a revolution round itself.

When we have arrived thus far, it becomes natural to ask whether we are to suppose that the separation of the light within the crystal has *given* poles to the molecules, or that the poles, already *pre-existing*, have merely been turned towards the same points of space. This question is a very difficult one; but we shall find hereafter, if not a demonstration of the second hypothesis, at least some plausible reason for adopting it. It will be here sufficient to remark, that the modification undergone by the rays is entirely independent of the nature of the crystal, provided that it only produce a double image; and that the phenomena presented by two rhomboids of calcareous spar, placed on each other, would be reproduced, with their minutest details, if we combined, for example, one of these rhomboids with a crystal of carbonate of lead; or if the first crystal were of sulphur, and the second of quartz or of sulphate of baryta.

Polarisation of light by reflection.

But it is not only in the phenomena of double refraction that the particular properties of polarised rays are exhibited; the *reflection* of these rays, at the surfaces of *transparent bodies*, affords also a method of *distinguishing* them from *common light*.

When a pencil of natural light falls on a transparent mirror, with any inclination whatever, it is divided into two parts; the one passes through the substance of the mirror, the other is reflected. This latter portion is always found in the plane passing through the primitive pencil, and the line perpendicular to the surface, which is called the *plane of reflection*, and which must be carefully distinguished from the *reflecting surface*.

If we now place the principal section of a doubly-refracting crystal in a vertical position, and throw a pencil of common light perpendicularly on its surface, receiving the two emerging pencils on the horizontal surface of some water;

and let us suppose the ordinary pencil to make with the surface of the liquid an angle of 37° 15′ [the crystal being held in a position inclined to the horizon]; this pencil will undergo a partial reflection like the direct light, while the extraordinary pencil, when its angle of incidence is also 37° 15′, will *enter the liquid completely, without the reflection of any of its molecules;* a character which constitutes a marked distinction between this pencil and the natural light.

All other circumstances of the experiment remaining the same, let us now cause the crystal to make one fourth of a revolution round the incident pencil, so as to bring the principal section into a position perpendicular to its first situation; we shall then find that the ordinary pencil alone will be entirely transmitted by the liquid; the other will undergo a partial reflection, exactly equal to that which we had first observed in the ordinary ray; the experiment affording a new proof, that the two rays only differ in the direction which is assumed by their corresponding sides.

We find also, that in all positions of the principal section, intermediate between these two, the two pencils will both undergo a partial reflection so much the stronger, for the ordinary pencil, as the principal section is the nearer to a coincidence with the plane of reflection, and for the extraordinary pencil, as these planes are more nearly perpendicular to each other.

We shall finish this section with an account of the mathematical law which appears to determine the comparative intensities of the ordinary and extraordinary pencils into which polarised light is separated when it is analysed with a doubly refracting crystal. Let F_o be the intensity of the ordinary pencil transmitted by any crystal, and F_{oo} and F_{oe} the intensities of the ordinary and extraordinary pencil derived from it in passing through the second crystal: let i be the angle formed by the two principal sections: then we shall have $F_{oo} = F_o \cos.^2 i$; $F_{oe} = F_o \sin.^2 i$.

In particular cases we shall have from these formulas, if $i = 0$, $F_{oo} = F_o$, $F_{oe} = 0$; if $i = 90°$, $F_{oo} = 0$, $F_{oe} = F_o$; and if $i = 45°$, $F_{oo} = \frac{1}{2} F_o$, $F_{oe} = \frac{1}{2} F_o$.

These three consequences of the formula, as we have seen, are conformable to observation. It will not, however, be proved to be mathematically exact, until we have also verified it for some values of i, intermediate between these limits.

The formulas belonging to the extraordinary ray are equally simple: F_e being the intensity of this ray, and F_{eo} and F_{ee} those of the two ordinary and extraordinary pencils into which it is divided by the crystal, i preserving its former signification, we shall have $F_{eo} = F_e \sin.^2 i$, and $F_{ee} = \cos.^2 i$. If $i = 0$, $F_{eo} = 0$, and $F_{ee} = F_e$; and in fact there is no ordinary ray in this case, the whole light following the extraordinary path: if $i = 90°$, $F_{eo} = F_e$, and $F_{ee} = 0$; which is again confirmed by observation, since the extraordinary ray, coming from a certain crystal, follows only the ordinary course in passing through another, of which the principal section is perpendicular to that of the first. The same agreement between the calculation and the experiment will be found when $i = 45°$; which, however, does not supersede the necessity of verifying these formulas, as well as the former, by direct experiments at intermediate angles.[1]

SECT. II.—OF REFLECTION, CONSIDERED AS A MODE OF POLARISING LIGHT.

Reflection, at the surface of a transparent body, affords, as we have seen, a *criterion* for the distinction of polarised from ordinary rays: we must also add, that such a reflection is also capable of polarising ordinary light.

Throwing, for example, a pencil of natural rays on a mirror of common glass in a horizontal position, in such a manner that the inclination of the ray to the surface may be about 35°; we shall find that a part of the pencil will pass through the glass, the other part will be reflected, and the reflected portion will be polarised in the same manner as the ordinary pencil transmitted by a crystal of which the principal section coincides with the plane of reflection.

In fact, if we analyse the light thus partially reflected, by the assistance of a crystal of which the principal section coincides with the plane of reflection, it is not subdivided, and affords only a single ordinary image. Nor is it again subdivided in passing through the crystal when the principal section is perpendicular to the plane of reflection; but in this case it only affords an extraordinary image. In every other position we have both an extraordinary and an ordinary image, the intensity of the latter being expressed by the formula, $F \cos.^2 i$; in which F is the total intensity of the pencil subjected to the experiment, and i the angle formed by the principal section of the crystal with the plane of reflection. This formula obviously coincides with that which we have given for the ordinary pencil in the case of two crystals combined. The plane of reflection here performs the office of the principal section of the first crystal; it is therefore in this plane that the ray has become polarised by the reflection.

Before we assert, however, that there is an identity in the species of polarisation effected by partial reflection with given inclinations, at the surface of a transparent body, and that which results from double refraction, we must submit the ray polarised by a first reflection to the test of new reflections.

These second reflections will obviously throw the light downwards if the mirror is above the ray, or upwards if below; from right to left if the mirror receives the ray on its [left-hand] surface, and the reverse if on the [right] surface.

Now, if the second mirror is above or below the ray, so that the new plane of reflection coincides with the old, there is a partial reflection at all incidences. But when, on the contrary, this mirror is presented to the ray on the left or the right side, and in such a manner that the new plane of reflection may be perpendicular to the old one, all reflection ceases at the inclination of about 35°, already mentioned. In the intermediate positions of the mirror, and with the constant inclination of 35°, the intensity of the reflection varies in proportion to the square of the cosine of the angle formed by the two planes of reflection with each other.

The least attention will show how much analogy this experiment has with those which have been made with a rhomboidal crystal. In those experiments, in order to see if the ordinary ray had the same properties with respect to each point of its circumference, we caused the crystal to revolve round the ray as an axis, so as to bring in succession its principal section, and consequently the poles contained in it, into a vertical direction, from right to left, and so forth; in these different positions we threw the ray on a transparent substance. Here we left the first plane of reflection immoveable, and the second turned round the

---

[1] See the article OPTICS, p. 462.

Polarisation of Light.

ray, which was thrown on its different sides. This trial is evidently similar to the former, and the result is identical.

We may therefore now affirm, that the ray which is reflected at the upper surface of the glass, with an inclination of about 35°, possesses in all respects the same properties as a ray transmitted by a crystal of which the principal section coincides with the plane of reflection.

We have supposed the substance employed in this experiment to be transparent; but we must add, that some opaque bodies, such as black marble, ebony, and some varnishes, possess in an equal degree the property of polarising rays which are reflected at their surface. These substances, when made to revolve round a polarised ray, exhibit the same effect, with regard to the reflected light, as the transparent substances which have been considered.

SECT. III.—OF RAYS PARTIALLY POLARISED.[1]

Rays partially polarised are those which possess properties that may be called intermediate between the properties of ordinary light and of light completely polarised. They are distinguished from polarised light by affording always two pencils in their passage through a crystal possessed of the property of double refraction; they differ from natural light in not affording always two pencils of the same intensity, in all positions of the principal section of the same crystal.

It may be asked, if a ray partially polarised may not be considered as consisting of a portion A of polarised and a portion B of natural light. This latter portion would *always* be equally divided into an ordinary and an extraordinary pencil, in its passage through a crystal possessing the properties of double refraction; the other would pass *sometimes* entirely as an ordinary or an extraordinary pencil. In a certain position of the principal section, therefore, the comparative intensities of the two pencils would be $\frac{1}{2}B + A$, and $\frac{1}{2}B$; and, after one fourth of a revolution, they would become $\frac{1}{2}B$ and $\frac{1}{2}B + A$ respectively. In all other positions, A would be divided between the two images; the portion belonging to the ordinary image being expressed by $A \cos.^2 i$, i being the angle contained by the plane of polarisation of A and the principal section of the crystal; and when $i = 45°$, the two images would be of equal intensity.

All these consequences of the hypothesis that we have assumed are conformable to experiment; and we may therefore suppose that a ray partially polarised is composed of two separate portions, the one, B, in its natural state, the other, A, totally polarised. (Sir David Brewster's experiments on partial polarisation will be mentioned hereafter.)

In every pencil reflected perpendicularly by a transparent substance, the portion A vanishes: it acquires greater and greater values in proportion as the angle of incidence increases; but at the angular situation of complete polarisation B vanishes, and A comprehends the whole pencil. Still farther from the perpendicular, we find again in the pencil natural light B, and polarised light A. Lastly, when the incident and reflected light sweeps, as it were, the surface of the mirror, A is again very inconsiderable with respect to B.

Metallic mirrors do not completely polarise the rays that they reflect at any angle of incidence. As in the case of transparent substances, A is evanescent for perpendicular rays; but it becomes sensible in every other case, and the light becomes partially polarised. The angle of polarisation of a metal is that which makes the quotient $\frac{B}{A}$ a maximum.

There exist also some transparent bodies, such as the diamond and sulphur, which never produce complete polarisation of the light that is reflected at their surfaces; but the quotient $\frac{A}{B}$ acquires, at least, much greater values for their substances than for the metals.

The mathematical law which connects the value of A with that of the angle of incidence, and of the refractive form of the mirror, has not yet been discovered. It is only known, that at regular angular distances above and below the angle of complete polarisation, the proportion of A to $A + B$ is nearly the same, although the absolute value of A and B may have changed very considerably.

Thus, in the case of the glass of St Gobin, for example, in which the complete polarisation takes place when the inclination of the ray to the surface is about 35°, we find that the reflected pencils contain the *same proportion* of polarised light at the following angles:—

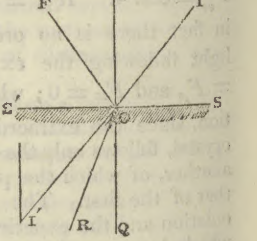
	65° 42′	63° 54′	60° 18′
and	7 12	7 55	11 40
mean	36 27	35 55	35 59

For water, the relation of A to $A + B$ is nearly the same at the angles 3° 29′ and 73° 48′; the mean of these, 38° 36′, exceeds by $1\frac{1}{4}°$ only the true inclination of complete polarisation, though it is deduced from angles which differ from it more than 30°.

In the same manner, therefore, as astronomers determine the instant of the passage of a luminary over the meridian, by corresponding altitudes, observed before and after that passage, we may obtain, with tolerable precision, the angle of complete polarisation, by taking the half sum of the inclinations corresponding to equivalent partial polarisations, especially if we take care not to deviate too far from the angle required; and this method has its advantages, when we make the experiment on bodies which do not polarise the rays of light completely at any incidence.

SECT. IV.—OF THE LAWS WHICH CONNECT THE REFRACTIVE DENSITIES OF BODIES WITH THE ANGLES OF POLARISATION.[2]

It is sufficient to look over the tables which have been published, of the angles of complete polarisation for rays reflected by substances of various kinds, in order to observe that these angles, reckoned from the perpendicular, approach so much the more to right angles, as the refractive densities of the substances are greater; but it was not so easy to detect the remarkable connection which exists between these two elements, and which we shall now proceed to examine.



When a ray of light, IO, passes from a vacuum into a certain medium, SS′, it is refracted at the point of incidence O, approaches to the perpendicular PQ, and follows, for example, the direction OR; the angles POI and QOR being for each medium connected by the proportion sin. POI : sin. QOR $= m : 1$, in which the quantity m is constant for all values of the angles. This quantity, which is always greater than unity, has been called the *index of refraction*, appropriate to the medium. It is necessary to distinguish it carefully from the refractive *power*, a numerical expression depending on m, and on the density, and chiefly relating to the particular properties attributed to refractive substances in the theory of emission.

---

[1] See the article Optics, p. 466, col. 2, and p. 469, col. 1.

[2] *Ibid.* pp. 463, 465.

This being understood, if the angle of incidence be supposed such, that the reflected ray OF may be completely polarised, it is found that *the tangent of the angle of incidence will be equal to the index of refraction.*

In the following table, the angles of polarisation, determined by experiment, are compared with those which result from the general law; and the errors are not greater than may be attributed to the unavoidable error of observation.[1]

Substances.	Observed Angle.		Computed Angle.		Difference.
Air	45° to 47°		45°		[1°]
Water	52	45′	53	11′	— 26′
Fluor spar	54	50	55	9	— 19
Obsidian	56	3	56	6	— 3
Sulphate of lime	56	28	56	45	— 17
Rock-crystal	57	22	56	58	+ 24
Topaz	58	40	58	34	+ 6
Iceland crystal	58	23	58	51	— 28
Ruby spinel	60	16	60	25	— 9
Zircon	63	8	63	0	+ 8
Glass of antimony	64	45	64	30	+ 15
Sulphur	64	10	63	45	+ 25
Diamond	68	2	68	1	+ 1
Chromate of lead	67	42	68	3	— 21

This law is capable of being expressed in other two remarkable forms.

Since in all cases sin. POI : sin. QOR $= m : 1$, we have universally sin. POI $= m$ sin. QOR; but for the angle of complete polarisation tang. POI $= m$, and since tang. $= \frac{\text{sin.}}{\text{cos.}}, \frac{\text{sin. POI}}{\text{cos. POI}} = m$, and sin. POI $= m$ cos. POI $= m$ sin. QOR, and sin. QOR = cos. POI, consequently QOR + POI = 90°; hence, *when the polarisation is complete, the inclination of the incident ray to the surface is equal to the angle of refraction; and the reflected and refracted rays are perpendicular to each other.*

It is of consequence to examine some objections which have been made to the accuracy of the law in question. If it were mathematically accurate, the rays of different colours, it has been observed, would not be polarised exactly at the same time, since they enter the refractive medium in different directions. Hence it would follow, that in the usual mode of investigating this angle of complete polarisation by analysing the reflected light with the assistance of a doubly refractive crystal, we ought not, in any case, to lose sight of one of the images; that when we arrived, for instance, at the angle which causes all the red light of the mixed pencil to be polarised, and to pass into the ordinary pencil, the observer ought to see an extraordinary image formed of the *white wanting the red*, that is, *green*; and the same for the other colours. Notwithstanding this, it has been added, in the greater number of cases, the crystal being properly arranged, one of the images is weakened by little and little, as we approach to the appropriate inclination, and at last disappears entirely without presenting any visible traces of colour.

It may be answered, in the first place, that there actually are substances in which this appearance of colour *is* manifest; and which, therefore, do *not* polarise the rays of different kinds at the same angle, but accord with the law of the tangent. Among others may be adduced the instance of specular iron ore, in which the phenomena is very striking; and the oil of cassia, of which the great dispersive power renders it also perfectly distinct. It may be added, too, that there is every reason to hope, that more accurate observations made with homogeneous light from different parts of the spectrum, and more precise measurements of the quantities of light that escape polarisation at inclinations approaching to that of complete polarisation, will hereafter remove the slight appearance of disagreement between experiments and a law too nearly approaching to the whole mass of the phenomena to be considered as otherwise than rigorously accurate.

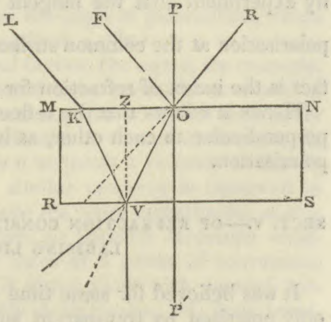
The table already inserted contains the names of several mediums, such as the diamond and sulphur, which do not completely polarise light; the law of the tangent *seems* therefore applicable to such mediums as these, provided that we understand, by the angle of polarisation, that in which the reflected pencil contains the greatest proportion of polarised light. In this case, the observation of this angle for metals would be the more important, as their refractive density has not been hitherto determined.

The angles of greatest polarisation, measured from the perpendicular, appear to be, for mercury, 76½°; for steel, above 71°; hence the index of refraction for mercury and for steel ought to be 4·16 and 2·85. [The oxide colouring the surface of heated steel has been found to give about 2·1 for its index, which agrees sufficiently well with this experiment.]

We have hitherto only spoken of the polarisation which takes place at the first surface of transparent surfaces entered by the light; the second surfaces possess analogous properties with respect to light passing out of them.

The angle measured from the perpendicular at which light is polarised when it is on its passage from a vacuum into a refractive medium, is greater than that in which the same phenomenon is observed when the light coming from the medium tends to pass into the vacuum; it is also shown by experiment that the *sine of the former angle is to the sine of the latter* as the index of refraction is to unity. We might express the same fact by saying, that at the second surface, as well as at the first, *the ray completely polarised* by reflection is perpendicular to the refracted ray. It follows, also, that if a medium is contained between two parallel surfaces, and if we throw a pencil of rays on the first surface, in the angle which affords complete polarisation, the transmitted portion of the pencil will also fall on the second surface in the angle which again produces complete polarisation.

Thus, if MN, RS, be the parallel surfaces, OR the incident ray, n the index of refraction, and OV the refracted ray; the angle of refraction VOP′ will always be equal to the angle OVZ, formed by the refracted ray with VZ, the perpendicular to the second surface. Now, according to the assigned law, when POR is the angle of complete polarisation for the first surface, sin. POR : sin. angle of polarisation at the second surface $= n : 1$, whence sin. POR $= n$ sin. angle of polarisation at the second surface. But from the law of the sines, as in the other cases, we have sin. POR : sin. VOP′ $= n : 1$, therefore sin. POR $= n$ sin. VOP



---

[1] See the article OPTICS, p. 464.

Polarisation of Light.

$= n$ sin. ZVO; an equation which, combined with the former, gives the angle of complete polarisation at the second surface = ZVO.

Hence it follows, that if the incident ray, being previously polarised, is such as to escape all partial reflection at its entrance into a substance terminated by parallel surfaces, it will also escape reflection upon its passage out of the substance.

If ROP has the appropriate value, OF becomes completely polarised, and VK likewise: the subsequent refraction in K makes no alteration in this ray; so that when we wish to procure polarised light by reflection from a transparent plate, there is no occasion to blacken the second surface of the plate; supposing it parallel to the first, the polarisation will be equally complete, and the reflected pencil will be brighter. It will only be proper to take care, by placing at a distance from the plate a black substance, as a piece of velvet, for example, to intercept the rays which might be transmitted by the plate from other objects beyond it.

The law from which these consequences have been deduced is only a particular case of a more general law, which may be thus enunciated.

The sine of the angle at which a pencil must be reflected at the first surface of a refractive medium, in order that it may contain a certain PROPORTION *of polarised light, is to the sine of the angle at which a reflection at the second face only would cause an* EQUIVALENT POLARISATION *in the same pencil, as the sine of incidence to the sine of refraction.*

It has been found by experiment, that the sine of the angle at which a certain proportion of a natural pencil is reflected at the first surface of a transparent substance, is to the sine of the angle at which an equal proportion of the same pencil would be reflected at the second surface, if it arrived there immediately, as the sine of incidence to the sine of refraction. This law of photometry, combined with the former, leads to a very simple enunciation.

The first and second surface of a transparent substance polarise light in an equal degree, at the same angles which enable them to reflect light in an equal degree.

We have now seen in what manner light is polarised, either in passing from a vacuum into a given substance, or in returning out of the substance into the vacuum. We must next examine the laws relating to the polarisation which occurs at the surface separating two mediums possessed of unequal refractive powers.

Let m and m' be the indices of refraction for the two mediums: suppose m to be greater than m'; it is proved by experiment that the tangent of the angle of complete polarisation at the common surface is equal to $\frac{m}{m'}$, [which in fact is the index of refraction for that surface].

Hence it follows that the reflected and refracted rays are perpendicular to each other, as in other cases of complete polarisation.

SECT. V.—OF REFRACTION CONSIDERED AS A MODE OF POLARISING LIGHT.[1]

It was believed for some time that the rays of light were only polarised by transparent substances in the act of reflection, and that the refracted pencil always retained the properties of ordinary light. But this opinion was erroneous. It is true, that the simple transmission of light through one or even two surfaces of any known substance is not sufficient for completely polarising a pencil of light; but at certain obliquities it occasions at least a partial polarisation; for, in examining the rays transmitted obliquely by a plate of glass with parallel surfaces, by means of a crystal possessed of the property of double refraction, it is found that the two images differ sensibly in intensity.

Let A' be the part of the transmitted pencil which is polarised, B' the portion of the same pencil not so modified, and A and B the analogous portions of the pencil reflected at the same incidence.

We have already said that A is polarised as an ordinary ray would be, transmitted by a crystal having its principal section coinciding with the plane of reflection; the poles of A', on the contrary, are placed like those of the extraordinary ray of the same crystal. If we analyse with a rhomboid the light reflected by a plate of glass, we find, for example, when in a certain position of the principal section, the image on the right hand is the more brilliant; and the relative position of the plate, the crystal, and the eye, remaining unaltered, it will be the opposite image, on the left hand, that will become the most conspicuous when we examine the transmitted light. All these results may be thus enumerated.

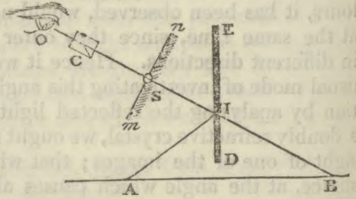
The plane which contains the poles of the transmitted light is perpendicular to that which contains the poles of the reflected light.

These different pencils are therefore polarised in directions at right angles to each other.

If we submit the reflected light $A + B$ to the action of a crystal of carbonate of lime, of which the principal section coincides with the plane of reflection, the intensities of the ordinary and extraordinary pencil will become $A + \frac{1}{2}B$ and $\frac{1}{2}B$.

In the same position of the plate and of the crystal, the intensities of the same images, furnished by the transmitted pencil, will be $\frac{1}{2}B'$ and $A' + \frac{1}{2}B'$.

A will therefore be the quantity by which the *ordinary* image, furnished by the reflected pencil, *surpasses* the extraordinary image, while A' will express, for the transmitted pencil, the quantity by which the *extraordinary* image will surpass the ordinary. With respect to this phenomenon, a remarkable result of experiment may here be noticed; that is, that in every possible inclination $A = A'$, or, in other terms, that the intensities of the two images afforded by the crystal differ in the same degree, whether we consider the reflected or the transmitted pencil.



Let us suppose that a plate of glass ED is placed in the position that the figure represents, before a medium AB of a uniform tint, for instance a sheet of fine white paper. The eye placed at O will receive simultaneously the ray IO, reflected at I, and the ray BIO transmitted at the same point. Place at mn an opaque diaphragm, blackened, and perforated by a small hole at S. Lastly, let the eye be furnished with a doubly refracting crystal, C, which affords two images of the aperture.

If, now, by means of a little black screen placed between B and I, we stop the ray BI, which would have been transmitted, the crystal, properly placed, will give an ordinary image $= A + \frac{1}{2}B$, and an extraordinary image $= \frac{1}{2}B$. But if the screen were placed between A and I, and the ray AI were intercepted, we should still have two images of the hole, and their intensities would be $\frac{1}{2}B'$ and $A' + \frac{1}{2}B'$

---

[1] See the article OPTICS, p. 470–473.

respectively. Consequently, without any screen, if the whole of the reflected light AIO and the transmitted BIO are allowed to arrive at the eye, we shall have for the ordinary image, $A + \frac{1}{2}B + \frac{1}{2}B'$, and for the extraordinary, $\frac{1}{2}B + A' + \frac{1}{2}B'$.

Now it appears, from actually making the experiment, that the two images are perfectly equal, whatever may be the angle formed by the ray AI with the plate of glass, which can only be because A is always equal to A'. Consequently,

The quantity of polarised light contained in the pencil transmitted by a transparent plate, is exactly equal to the quantity of light polarised at right angles, which is found in the pencil reflected by the same plate.[1]

Hence it follows, that at the angle of complete polarisation by reflection, the two images of the transmitted pencil given by a crystal properly placed, differ in intensity by a quantity equal to the whole of the reflected pencil. So that if ever a body should be discovered that could reflect half of the light incident at this angle, the pencil transmitted, at the same inclination, would also be completely polarised.

In order to simplify this reasoning, we have supposed throughout that there was only one efficient surface in the plate ED; it would be entering into too much detail if we proceeded to demonstrate in what manner this supposition might be justified; and it will be sufficient to remark, that the experiment in question succeeds equally well when ED is a simple plate of glass with parallel surfaces, which implies that the second surface polarises also equal quantities of light by reflection and by refraction. But, lastly, in order to remove every doubt respecting the accuracy of these results, it may be added, that when some natural light, and some light that had passed through a rhomboid of carbonate of lime, was thrown on a plate of glass reflecting at one of its surfaces, or at both, it was found that the reflected light contained the same quantity of polarised rays in both cases. Now the reflecting plate exercises no particular action on the two equal pencils of light transmitted by the rhomboid, and polarised in directions perpendicular to each other; it only divides them unequally; and if the reflected pencil contains an excess of rays polarised in one direction, there will be found in the transmitted pencil an excess precisely equal, of rays polarised in the direction perpendicular to it. In this case, the law here laid down must necessarily be true; and in order to extend it to natural light, it is sufficient to have assured ourselves, as we have done, that it is affected in the act of reflection and in that of refraction, precisely in the same manner as the combination of two equal pencils polarised at right angles to each other.

One of the best modes of verifying the accuracy of physical laws is, to inquire what their results are in extreme cases. The law now in question, supposing it universally true, leads us, for example, to this conclusion, that where there is no transmission of light, there can be no polarisation; and, in fact, if we cause a pencil of light to fall on the interior surface of a prism, at an inclination which produces complete reflection, we shall find no trace of polarisation in the reflected pencil, although, at incidences but little different, a considerable part of the light, and even the whole, may have been polarised.

Let us represent by A the part of the pencil I which is polarised by reflection, at the angle of 35° from the two surfaces of a plate of glass; the pencil transmitted will be $I - A$: now in this quantity of light there will be, according to the law laid down, A rays of which the plane of polarisation is perpendicular to that of the reflected rays, so that the quantity of natural light remaining will be $I - 2A$, which we may call $= I'$. Then the pencil $I' + A$ falling on a second plate, parallel to the first, and consequently at the same angle as before, A will entirely escape the partial reflection, and, abating what may be lost by absorption, will be found entire in the pencil transmitted by the second plate; I' will be divided in the same manner as I was at first; a portion A' of I' is polarised by reflection, the remaining portion $I' - A'$ is transmitted, and will contain A' of polarised rays, so that the natural light, after passing through the second plate, will be reduced to $I' - 2A'$, and the quantity polarised by refraction will be $A + A'$. Making $I' - 2A' = I''$, the light $I'' + A + A''$ will furnish, in its passage through a third plate, parallel to the two former, a new quantity A'' of light polarised by refraction, which will be added to $A + A'$, and so forth.

The pencils, I, I', I'', and so forth, consisting of natural light, are polarised in equal *proportions* by the respective plates: the quotients $\frac{A}{I}, \frac{A'}{I'}, \frac{A''}{I''}$, will constantly have the same value. If, for instance, $\frac{1}{6}$th part of the pencil I is polarised by reflection at the surfaces of the first plate, $\frac{1}{6}$th of I' will be polarised at the surfaces of the second, $\frac{1}{6}$th of I'' by the third, and so forth; and the pencils transmitted by these same plates will contain respectively of natural light, or of light possessing the same properties, $\frac{4}{6}$ths of I, $\frac{4}{6}$ths of I', $\frac{4}{6}$ths of I'', and so forth. Hence, whatever may be the number of plates employed, the pencil ultimately transmitted will contain, mathematically speaking, a certain quantity of natural light; but this quantity will be rapidly diminished, and will finally become completely insensible. [Sir David Brewster, on the contrary, maintains that it wholly disappears after transmission through a finite, and even a moderate number of plates.]

It may be said, in this sense, that a pile of parallel plates polarises the light which passes through them, in a direction perpendicular to the plane in which the rays would be polarised by reflection at the same surfaces.

We have here supposed the incident light to meet the plate of glass at the inclination capable of polarising it completely by reflection; but the same result is obtained whatever the inclination may be. It is only necessary that it should be composed of a number of elements, so much the greater as the direction of the rays is nearer to the perpendicular.

With a given inclination, the number of plates necessary to produce by transmission a polarisation nearly complete, depends also on their reflective power: we have already observed, for example, that a single plate, capable of reflecting half the incident light at the angle of polarisation, would of itself be sufficient to constitute a pile.

There are certain natural bodies, the agate, for example, which modify the transmitted light precisely as a pile of plates would do. If we cut a plate of agate sufficiently thick, in a direction perpendicular to that of its laminæ, the light which passes through it acquires a polarity in the direction of the plates. A similar property is observed in the tourmaline, and it is here the more remarkable, as this mineral, when pure, exhibits no lamellar structure whatever. If the two opposite faces of a prism of tourmaline are polished so as to form it into a plate with parallel surfaces about $\frac{1}{25}$th of an inch in thickness, the light transmitted by it, whatever its angle of incidence may be, will be polarised in a direction perpendicular to the axis of the column.

It will be proper to mention here the phenomena exhibited by piles of plates when they are exposed to rays that have been previously polarised: supposing always that the pile is formed of parallel plates of glass; and, besides, that the angle of inclination to the first surface is about 35°, reckoning from the surface itself.

---

[1] See the article OPTICS, p. 473.

If the primitive plane of polarisation of the incident ray coincides with the plane drawn through this ray and the perpendicular to the first plate at the point of incidence, a part of this ray more considerable than if we employed natural light will be reflected; at the point of incidence on the second plate, the luminous pencil transmitted by the first will undergo reflection in the same proportion as the former pencil; the same effect will take place in the third plate, and so forth. The transmitted ray, however intense it may have been in the first instance, will thus be gradually weakened in a geometrical progression, and at last will become insensible; so that if we look at the pile on the opposite end, it will appear to be an opaque body, perfectly impervious to light.

Everything else remaining in the same state, if we turn the pile round the ray as an axis through an angle of 90°, the new plane of reflection will be perpendicular to the former, and the plate will have reached the situation which has been already mentioned, in which the reflective property wholly disappears, and the whole of the light will pass through it. But the second plate, the third, and all the following plates, which are parallel to the first, will be found in the same circumstances possessing the same properties, and will not reflect any of the incident light; so that, setting aside the effect of absorption, the apparatus actually transmits light without weakening it.

The pile of plates possesses, therefore, with respect to polarised light, the singular property of being either completely opaque or perfectly transparent, according to the side which it presents to the light, notwithstanding that the inclination of the light to the first surface remains constantly 35°. In the intermediate positions the quantity of transmitted light increases gradually as we proceed from that in which nothing is transmitted, to the other extreme in which the light is only weakened by absorption.

Tourmalines and agates appear to be true piles of plates, so that they must produce similar effects; and, in fact, a plate cut, for example, in a direction parallel to the axis of a column of tourmaline, transmits rays which are polarised in a plane perpendicular to the axis, and totally stops, on the other hand, rays of which the primitive plane of polarisation is parallel to that axis.

When we place such a plate between the eye and a reflecting surface of water or glass situated in the open air, and look at it with an inclination producing complete polarisation, it appears either fully enlightened or quite dark, or in intermediate states, according to the situation of the plate in its own plane. A circumstance which adds to the singularity of this experiment is, that it succeeds completely even when the incidence on the plate is perpendicular; while for a pile properly so called, unless it be composed of an immense number of plates, it is necessary that the distance of the ray from the perpendicular should be very considerable.

Whatever may be the cause of these phenomena, it results evidently, from what has been mentioned, that two plates of tourmaline placed so that their axes form a right angle, must compose a system perfectly opaque with respect to light of all kinds. If, for example, the incident light is in its natural state, it is obvious that the portion transmitted will be polarised in the direction of the axis of the plate, and that the second plate, situated in a perpendicular direction, will consequently stop the whole of the light so polarised.

SECT. VI.—OF THE DEPOLARISATION OF LIGHT.[1]

After having examined in what manner ordinary light is converted into polarised light, we must now proceed to study the modifications which this latter undergoes in its turn when it is subjected to reflection or refraction at surfaces of different natures, and differently situated with respect to its poles.

When a polarised pencil falls on the surface of a well-polished mirror, in such a manner that its plane of polarisation coincides with the plane of reflection, or is perpendicular to it, the light regularly reflected at this surface is completely polarised, like the incident pencil, in a direction parallel or perpendicular to the plane of reflection; and this happens whatever the nature of the mirror may be.

But whenever the primitive plane of polarisation of the incident pencil is any otherwise situated, it will be found that the reflected pencil is modified, and the modification will depend on the nature of the mirror.

When we employ for these experiments a mirror either transparent or opaque, which is capable of *completely polarising natural light*, the rays previously polarised which fall on this surface will *again be completely polarised*, after their reflection, but *not in the plane of their primitive polarisation.* This *deviation* of the plane of polarisation of a luminous pencil, produced by its reflection at the first surface of a transparent mirror, depends both on the angle of incidence and on the direction of the plane of reflection with regard to the poles of the ray.

For given inclination, the deviation is so much more considerable as the plane of reflection makes with the plane of primitive polarisation an angle more nearly approaching to 45°.

Let us first suppose, in order to assist the imagination, that the reflecting surface is horizontal; that the eye of the observer, and the rhomboid which is to furnish the polarised pencil, remain constantly situated, the one to the north, the other to the south of the point of reflection, so that the plane of reflection may always coincide with the meridian; and that, lastly, the principal section of the crystal, which contains in its plane the poles of the ordinary pencil, makes an angle of 45° with the meridian.

When this ordinary pencil falls perpendicularly on the mirror, it will be reflected without any deviation of its plane of polarisation: so that this plane, having at first formed, by the suppositions, an angle of 45° with the meridian, the inclination to the meridian will remain the same after the reflection.

If we cause the direction of the incident light to vary more and more from the perpendicular, we shall first remark that the plane of polarisation of the reflected light approaches by degrees to the plane of reflection, and that it coincides exactly with it when we have arrived at the angle of complete polarisation; that afterwards the reflected ray is polarised in a plane which is more remote from the plane of reflection in proportion as it forms a smaller angle with the surface of the mirror; and that at last, when the ray is nearly parallel to the surface, its plane of polarisation coincides with that of the incident light, as it did when the incidence was perpendicular.

Let us call the angle of incidence, reckoned from the perpendicular, i, the corresponding angle of refraction for the substance concerned, i'; the tangent of the angle formed by the plane of polarisation of the reflected light with the plane of reflection will be expressed by $\frac{\cos.(i+i')}{\cos.(i-i')}$.

---

[1] See the article OPTICS, p. 470.

This formula may be illustrated by applying it to particular cases. If $i = 0$, i' being also $= 0$, $\frac{\cos.(i+i')}{\cos.(i-i')} = 1$; but the angle of which the tangent is unity is an angle of 45°. Consequently, if the formula is correct, the plane of polarisation for the reflected ray, when the incidence is perpendicular, must coincide with the primitive plane of polarisation of the light employed; and this is conformable to observation.

The angle of which the tangent is $\frac{\cos.(i+i')}{\cos.(i-i')}$ becomes also 45° when $i = 90°$; that is to say, when the rays are parallel to the surface concerned, since then $\cos.(i+i') = -\cos. i'$, and $\cos.(i-i') = +\cos. i'$. The light preserves, therefore, in this case also, its primitive plane of polarisation, as the experiment had shown.

If $i+i' = 90°$, the angle of i, as it has already been observed (Sect. III.), is that of complete polarisation, and $\frac{\cos.(i+i')}{\cos.(i-i')}$ is $= 0$; so that the plane of polarisation of the reflected ray coincides with the plane of reflection, which has already been shown by experiment.

The following table will show that, for intermediate angles of incidence, the agreement between this mode of calculation and the observation is as satisfactory as it was possible to expect.

On Glass.

Angles of Incidence.	Observed Deviation of the Plane of Polarisation.	Computed Deviation.	Difference.
24°	38° 55′	37° 54′	+1° 1′
39	24 35	24 38	—0 3
49	11 45	10 52	+0 53
56½	0 0	0 0	0 0
60	5 15	5 29	—0 14
70	19 52	20 24	—0 32
80	32 45	33 25	—0 40
85	38 55	39 19	—0 24
87	40 55	41 36	—0 41
88	41 15	42 44	—1 29
89	44 35	43 52	+0 43

On Water.

Angles of Incidence.	Observed Deviation.	Computed Deviation.	Difference.
53°	0° 0′	0° 0′	0° 0′
60	10 20	10 51	—0 31
70	25 20	24 48	—0 32
80	36 20	35 49	+0 31
85	40 50	40 32	+0 18

The formula, thus compared with experiment, supposes that the primitive plane of polarisation of the light employed *makes an angle of* 45° *with the plane of reflection;* but a slight addition is sufficient to accommodate it to all other cases. If we make a the angle of which the particular value is here assumed 45°, i and i' retaining their values, the tangent of the angle expressing the deviation of the plane of polarisation of the incident pencil, after reflection, will in general be represented by $\frac{\cos.(i+i')}{\cos.(i-i')}$ tang. a.

It is easy to observe, that, in the most material cases, this formula correctly corresponds with the experiments; but we are still in want of an experimental demonstration of its truth for any very diversified combinations of the values of a and i.[1]

The deviations of the planes of polarisation follow the same gradations when the reflection takes place at the second surface of transparent mirrors, from the position of perpendicular incidence to that of the beginning of total reflection. But beyond that inclination the phenomenon acquires a character totally different: we have then no longer a simple change of the direction of the primitive poles of the ray; for unless the plane which contains the poles either coincide with the plane of reflection or be perpendicular to it, the ray will undergo a true depolarisation, so that however we place the rhomboid through which we cause it to pass, we shall always observe that two images are formed. The same happens also when the mirror is metallic. The particular and very remarkable modifications which the light undergoes in these two cases will shortly be mentioned.[2]

SECT. VII.—OF THE PHENOMENA OF INTERFERENCE, SO FAR AS THEY ARE MODIFIED BY A PREVIOUS POLARISATION OF LIGHT.[3]

It has long been known [having, however, first occurred to the translator of this article in the room and at the table on which he is now writing], that if, after having cut in a thin plate of metal two very fine slits very near to each other, we cause them to be enlightened by a pencil proceeding from the same radiating point, we may observe behind the plate a formation of iridescent fringes, derived from the action exerted by the rays scattered from the left-hand slit on the rays scattered from the right-hand slit, in the points where these two parcels of rays are intermixed.

This experiment, when studied in all its details, has led to the simple law, which may be thus enunciated: Two rays of homogeneous light, *proceeding from the same source*, and arriving from a given point of space by two different routes, a little unequal in length, co-operate with each other, or are destroyed, and form, on a screen which receives them, either a bright or a dark spot, according to the magnitude of the difference of their routes.

The two rays always co-operate completely when they are united after passing through a route of equal length. If the smallest difference of routes, which will cause them again to co-operate, be called d, they will co-operate whereever the distance is any member of the series $2d$, $3d$, $4d\ldots$; and the intermediate values $0+\frac{1}{2}d$, $d+\frac{1}{2}d$, $2d+\frac{1}{2}d\ldots$, will show the cases in which the two rays, when combined, produce darkness. The magnitude of the quantity d varies with the species of light concerned, and with the nature of the medium which transmits it.

If two rays destroy each other after having passed through routes differing, for example, by the quantity d', they will also destroy each other after having passed through, either perpendicularly, or with the same obliquity, two plates of *the same nature, and of the same thickness.*

A difference of thickness, or of refractive density, in the two plates interposed, may produce the effect of an inequality in the routes described: the difference will give rise, in certain cases, to a displacement only of the fringes; but in others they will entirely disappear.

These laws relate to the rays of light in their natural state; if we employ polarised light, we obtain results which, independently of the numerous applications of which they are susceptible, deserve for their singularity to arrest our attention.

---

[1] Such experiments will be found in the article OPTICS, p. 465, 466; and in the same article the reader will find a new formula, confirmed by numerous experiments, exhibiting the deviations of the planes of polarisation produced by *refraction.*

[2] See the article OPTICS, p. 505.

[3] Ibid. p. 426 and 497.

Let us first suppose, that instead of enlightening *the two* slits of the plate of metal with natural rays, we employ polarised light, the fringes will be formed equally in both cases.

If we then try the effect of the light polarised in one direction and transmitted by one of the slits on the light polarised in a perpendicular direction, and transmitted by the other; an arrangement which may be obtained by placing two piles properly directed in the passage of the different rays; we shall find, that when the directions are correctly perpendicular, there is no trace of fringes behind the perforated plate.

It has been remarked, that any material difference in the mediums through which the two rays pass, is sufficient to annihilate the effects of interference which would otherwise be observable. The experiment now mentioned would therefore be wholly inconclusive, if we had not previously assured ourselves that the piles, which are supposed to be of the same nature, are also exactly of the same thickness. The best mode of ascertaining this is evidently to render the two planes of polarisation parallel: if in this case we perceive fringes, and if, after having turned one of the piles one fourth of a revolution round its axis without changing their mutual inclination, we find that they disappear, we may fairly conclude that this disappearance must be attributed to the direction of the polarisation of the rays of light concerned.

This experiment would be a very difficult one to make with success if the piles had any considerable thickness; but they may be made very thin by means of plates of mica, or of bits of glass blown in a lamp; and then, by dividing them in the middle, we may obtain a pair of piles of thicknesses perfectly equal. Besides, nothing prevents our varying gradually the inclination of one of the piles, so as to compensate in this manner for the effect of a slight difference of thickness, if it exists.

But there is another mode of observation which is more convenient. We take a crystal of tourmaline cut in a direction parallel to its axis, so as to form a plate with parallel surfaces; we divide it into two parts, and apply the two portions, one to the slit on the right hand of the plate, and the other to that on the left. We then find that fringes are produced when the two axes of the fragments are parallel, and that no traces of them are left when they are perpendicular to each other; and that in changing the positions of the portions of tourmaline from one of these relations to the other, the intensity of the fringes gradually disappears.

Supposing now the piles to remain fixed to the slits in perpendicular directions, so that no fringe may be visible; and placing a third pile before the eye of the observer, in a plane that forms an angle of 45° with the planes of incidence of the two former; this last plane must reduce to a similar polarisation the rays coming from the two slits, which before they met were polarised at right angles; so that there seems to be no reason why the rays should not again interfere: and yet whatever pains we take in the experiment, we shall discover no trace of fringes. [Might there not, however, be fringes if the rays met behind the third pile rather than before it? Tr.]

It is unnecessary to remark, that a tourmaline of any kind may be substituted for the third pile, as the two former may be exchanged for the two halves of a piece of tourmaline with parallel surfaces: the result will be precisely the same.

Let us lastly suppose, in order to exhaust all possible combinations, that the plate of metal is illuminated with polarised light, and that two piles or two tourmalines are so placed as to transform the rays passing through the two slits from rays polarised in the same direction, into rays polarised in directions at right angles to each other; and that, before the interference of the rays, we bring them back to a similar polarisation, either by the assistance of a third pile, or by that of a tourmaline, as in the former experiment: the observer will then find, and no doubt with great surprise, that the rays are again susceptible of interference, or that in mixing together they produce a very visible group of iridescent fringes.

The series of experiments here related leads us to the following conclusions.

1. Two pencils converted from natural light into light polarised in the same direction, retain, after this modification, the property of interfering with each other.

2. Two pencils, which are made to pass directly from the state of natural light to that of light polarised in two perpendicular directions, are no longer capable of interference, either while they remain in this state, or after they have been restored to a similar polarisation.

3. Two pencils polarised in contrary directions do not interfere, whatever may have been the modifications that they have undergone before they arrive at this state from that of natural light; but when restored to a similar state of polarisation, they become capable of interfering, provided that, in their passage from the natural state to that of polarised light, THE FIRST planes of polarisation of the two pencils were parallel.

Thus it appears, that in these phenomena the mode of action of the rays does not depend on *what they are* only when they meet, but also *on what they have previously been.*

SECT. VIII.—OF THE KIND OF POLARISATION WHICH IS EXHIBITED IN THE APPEARANCE OF COLOURS, AND WHICH HAS THEREFORE BEEN CALLED COLOURED POLARISATION.[1]

We may first examine the *nature* of the new modification of light that is concerned in these appearances; and, secondly, the *means* of producing it.

Supposing a ray of direct light to be polarised in any of the ways that have been described, and then to pass through a plate of rock-crystal cut perpendicularly to the edges of the hexaedral prism, about a quarter of an inch in thickness, and having both its surfaces perpendicular to the ray: when it emerges from the surface, it will no longer possess the properties of common polarised light; and yet it will not have re-assumed the characters of direct light: for if we submit it to the action of a rhomboid of carbonate of lime, instead of affording one image only in a particular position with respect to the principal section of the crystal, it will be *constantly* subdivided into two pencils; so that it cannot be identical with common polarised light.

Neither is it simply natural light; for a white pencil of natural light is always divided, by a doubly refracting crystal, into two white pencils of equal intensity. The white pencil which has passed through the plate of quartz, on the contrary, gives always two images, but they are distinguished by the most vivid colours. If the ordinary image is red, the extraordinary is green, and the reverse: and the case is the same with regard to the other prismatic colours; that of the ordinary pencil is complementary to the tint of the extraordinary pencil, and they both vary according to the position of the principal section of the rhomboid which causes the separation.

The prismatic telescope of M. Rochon affords an apparatus perfectly adapted to the performance of these experiments, and which requires to be mentioned, first, because it exhibits the tints with great brilliancy; secondly, because it gives us the means of assuring ourselves that the images viewed lose nothing of their distinctness by the interposition of the plate, and that its effect is not owing to any irregular dissipation of the light concerned; and, thirdly, on account of the facility with which it allows us to show that the tints are complementary to each other.

---

[1] See the article Optics, p. 476–501.

This instrument is nothing more than an ordinary telescope, furnished, between the object-glass and the eye-glass, with a prism of rock-crystal or of carbonate of lime rendered achromatic. This prism being moveable at pleasure along the axis of the telescope, the observer is enabled to separate more or less, at his pleasure, the two images of the object which he is viewing.

Having, then, before the object-glass of this telescope the plate of quartz in question, and adapting besides to the eye-glass a greenish dark glass of a particular kind, which is much employed by astronomers because of its property of absorbing a good deal of light, without sensibly colouring the transmitted pencil; if we observe the sun directly with this instrument, we shall see two images of the sun, both white, and of equal brightness, whence it follows that the plate produces no particular effect on natural light; but if, on the contrary, we look at the sun's image as reflected by a plate of glass not silvered, we shall perceive two more suns, each of them coloured; and whilst the telescope performs half a revolution on its axis, they will both run through nearly the whole series of the prismatic colours. Thus, the image that was red, will become successively orange, yellow, greenish-yellow, bluish-green, and violet: and at this period the telescope will have made half a turn; its movement being continued, the violet image will become first red, then orange, and so forth. The second image will always give us the complementary colour; for if, instead of completely separating the images, we allow them to overlap each other, the part common to both the discs will remain constantly white, while the remaining lunular portions will exhibit the most vivid colours.

The reflection of a transparent plate may also be employed for more directly exhibiting the distinctive properties of the light transmitted by the plate of quartz.

If we cause a plate of glass to turn round a pencil of natural light forming with its surface an angle of about $35\frac{1}{2}$°, the reflected pencil will be directed in succession to all the points of the horizon, but it will constantly preserve *the same intensity*.

But if the incident pencil is polarised, we shall find, on the contrary, two positions diametrically opposite to each other, in which the mirror will not reflect *a single ray*.

Making, now, a similar experiment with the light that has been transmitted by a plate of rock-crystal, we shall see that it becomes coloured by reflection, though it falls white on the plate, and that the nature of the *colour* depends on *the side of the ray* that is presented to the reflecting surface. These reflected colours succeed each other during the revolution of the plate, in the same order as in the prismatic spectrum; and they are also observed in the transmitted light, being always complementary to those of the light reflected at the same time.

If the properties of polarised rays depend, as is supposed by the partisans of the system of emission, on the particular arrangements assumed by the molecules of which they are formed, it will be easy to describe the intimate composition of the ordinary polarised ray, and that of the same ray after it has passed through the plate of rock-crystal: in the former, the axes of all the molecules of the different colours must be parallel; in the latter, the molecules of different tints must have their poles turned towards different parts of space.

It now becomes necessary to examine according to what law the direction of these poles is varied, both as they depend on the particular tint of each molecule, and on the greater or less thickness of the crystal that they have passed through.

If we employ homogeneous polarised light, we shall readily find, that, supposing a given plate of quartz to turn the poles of a certain ray of light through an arc of 20° from their primitive direction, a plate of the same crystal twice as thick will cause a double deviation, and will turn the pole through an arc of 40°; a plate of thrice the thickness will cause a triple deviation, amounting to 60°; and so forth, without limit.

With regard to the simple rays of different colours, in passing through a given plate, they undergo deviations so much the more considerable as they are more refrangible, and this in the inverse proportion of the numbers which Newton calls the lengths of the fits; or, what comes to the same result, in the inverse proportion of the quantities which have been designated in this article by the letter *d*. (Sect. VII.)

When, therefore, we know the deviation for a given plate, we may find the effect of a thicker or thinner plate of the same substance by a simple proportion.

Table of the Deviations of the Planes of Polarisation of the different "Homogeneous" Rays in passing through a Plate of Rock-Crystal perpendicular to the Axis of the Prism, of which the thickness is a millimetre, or ·03937 E. I. [according to the Newtonian division of the spectrum].

Extreme red	17·50°
Limit of red and orange	20·48
...... orange and yellow	22·31
...... yellow and green	25·68
...... green and blue	30·05
...... blue and indigo	34·57
...... indigo and violet	37·68
Extreme violet	44·08

There is no reason to suppose that the angular deviations will undergo any alteration in their values when all the molecules pass through the crystal at the same time. Consequently, in the white pencil transmitted by a plate of a millimetre, the axes of the elementary red rays will form an angle of 8° with the axes of the first orange rays, of about 5° with those of the first yellow rays, and of 26·5° with the axes of the extreme violet rays; and if we analyse this white pencil by means of a rhomboid, the differently coloured rays will not be divided in the same proportions between the two images: hence there will necessarily be appearances of colour. It is obvious, for example, that when the rhomboid is so placed that its principal section shall coincide with the poles of the red ray, this ray will remain altogether in the ordinary pencil, and the red tint will be wholly wanting in the extraordinary image.

We may obtain an exact idea of the modification which a plate of quartz produces in a white pencil of polarised light, by conceiving a combination of red rays polarised by reflection at the surface of a certain transparent substance, of orange rays polarised by a second surface placed in a different angular situation, of yellow rays polarised by a third surface, and so forth. The necessity of the intimate mixture of all these kinds of molecules in each line of white light, and some other obstacles, would render it impossible to realise this fiction without a very complicated apparatus; while a simple plate of quartz is sufficient, on the other hand, to give to the different constituent parts of the white pencil these individual polarisations situated in different azimuths.

The phenomena which have been described are produced by plates of quartz with parallel surfaces cut perpendicularly to the axis of the hexaedral prism. Now, in a direction perpendicular to these surfaces, quartz exhibits no double refraction; so that the causes which in this case produce the deviation of the planes of polarisation of the luminous molecules, are different from the causes which occasion the separation of the two pencils in other sections of the crystal. And it is remarkable that the properties of these plates have been found in bodies not possessed of regular crystallization, as flint-glass, and even in perfect fluids, such as the essential oils of turpentine and of lemons, or the solution of camphor in alcohol, the simple syrup of sugar, and so forth. The only difference is in the absolute value of the thicknesses which afford the same tints, the other laws remaining the same. Thus the thickness of oil of turpentine must be sixty-nine times as great as that of a plate of rock-crystal to produce the same effect; and the action of the oil of lemons is to that of the oil of turpentine as seventeen to ten [or to that of crystal as one to forty-one].

We have seen that a plate of quartz a millimetre in thickness causes the poles of the red molecules to describe an arc of 17·5°. We may suppose this motion to have taken place from right to left: then every other plate, of whatever thickness, cut out of *the same* crystal, will cause the poles to deviate still farther in the same direction, that is, to turn still from right to left; whilst other plates, on the contrary, cut out of a different crystal, may turn them from left to right. This phenomenon, at first sight, must appear very singular; but if we reflect that the rays pass through the plates in a direction which affords no double refraction, we shall be aware that a deviation of the poles directed constantly the same way in every specimen of the crystal would be not at all less astonishing.

It has not hitherto been possible to point out any exterior signs which shall indicate the direction of the deviation that will be produced by a given crystal, except in one very remarkable case. In some varieties of quartz, the solid angles, situated at the base of the pyramid by which the prism is terminated, are replaced by as many facets placed obliquely with respect to the edges. Now the direction of the deviation which these *plagiedral* crystals give to the poles of the luminous molecules, is constantly that of the obliquity of these little facets.

When a polarised ray passes successively through two plates producing contrary rotations, the ultimate deviation of the poles is the difference of the effects which each plate would have produced separately. The ray exhibits exactly the same tints as if it had passed through a single plate, of a thickness equal to the difference of the thicknesses of the two plates.

If the plates thus combined are equal in thickness, the pencil transmitted, having been turned first in one direction, and then turned back in the contrary direction, seems not to have its polarisation ultimately changed.

The essential oil of turpentine causes the axes of the molecules of the polarised ray to turn from the right to the left of the observer receiving the ray; the essential oil of lemons from left to right. These fluids do not lose their peculiar properties when they are mixed; so that if their proportions in the mixture are inversely as their rotatory forces, the ray which has passed through them retains its primitive polarisation.[1]

SECT. IX.—ON THE PHENOMENA OF DEPOLARISATION, AND OF COLOURS PRODUCED BY CRYSTALLIZED PLATES NOT CUT PERPENDICULARLY TO THE AXIS OF DOUBLE REFRACTION.[2]

We are next to inquire how a white pencil, polarised in a single direction, is modified in passing through a crystalline plate possessed of double refraction.

For this purpose we may place the principal section of a rhomboid of calcareous spar in the plane of polarisation of a white pencil, which of course will be subjected to the ordinary refraction only: we may then place the plate in question before the rhomboid, so that the rays may pass through it perpendicularly. If now the principal section of this plate is parallel to that of the rhomboid, we shall still see but one white image; and the same will happen if the principal sections are perpendicular to each other; but in every other situation of the plate, the rhomboid will furnish two pencils, and they will be distinguished by *complementary tints.*

The motion of the plate in its own plane does not alter the *nature* of the tints: their brightness only varies, and becomes greatest when the angle formed by the two sections is equal to 45°.

These tints vary with the thickness of the plate, and degenerate into perfect whiteness when the thickness becomes considerable. In the sulphate of lime, the appearances are no longer observable when the thickness is about half a millimetre, or one fiftieth of an inch.

Supposing O to be the tint of the ordinary pencil, and E that of the extraordinary; the experiment shows that the tint E is nearly that of one of the coloured rings seen in the light reflected from two object-glasses touching each other, as in the celebrated experiments of Newton; and that the tint O is that of the corresponding transmitted ring. This rule, however, is not perfectly general; for in many crystals the tints E by no means resemble those of the rings.

When the regular sequence of the Newtonian rings is observable, the successive thicknesses of the same crystal, which afford the respective colours E, are proportional to those which Newton has assigned for substances not crystallized: it is only found that, for any given density, the absolute values of these thicknesses greatly surpass the thicknesses shown in the Newtonian tables.

We find also a remarkable relation between the tint E, the thickness of the plate, and the elements of its double refraction, which it is important to point out. The image E only appears when the principal section of the plate is neither parallel nor perpendicular to the primitive plane of polarisation of the ray which passes through it. If we suppose this plate to possess only the ordinary properties of double refraction, the ray will in general be divided by it into two pencils, one of which will be refracted ordinarily, the other extraordinarily; so that two pencils from the same origin meet, after having passed through different routes, and *interfere.* There is a certain inequality of the lengths of these paths at which the red rays destroy each other; at another interval the yellow rays, the green, the blue, and so forth. If we determine, from these principles, the tint resulting from the interference of the different rays, taking into account the thickness and the intensity of the double refraction of the plate, we shall always find a very satisfactory agreement between the calculation and the experiment. (See the article CHROMATICS.)

The singular deviation which these thin plates seem to produce in the poles of the molecules of different colours which constitute white light, was extremely difficult to be discovered; and nothing shows this difficulty better than the general assent of natural philosophers to the laws which have been the foundation of the *theory of moveable polarisation.* It is not therefore sufficient to explain here the true principles on which these phenomena are founded: the confutation of an erroneous theory becomes absolutely necessary in this stage of the investigation, especially when it is plausible in appearance, and when it is brought forward with confidence in the latest works, notwithstanding the decisive objections which had been opposed to it.

---

[1] See the article OPTICS, p. 504, col. 2.

[2] Ibid. p. 476.

The fundamental theorem of this *moveable polarisation* has been thus enunciated. "When a ray of natural light, polarised in a certain fixed direction, passes perpendicularly through a crystallized plate, which is parallel to the axis of double refraction, the molecules of light penetrate at first to a certain distance without losing their primitive polarisation: after this they begin to perform periodical oscillations round their own centres, so that their axis of polarisation is carried alternately on each side of the principal section of the crystal, or of the line perpendicular to it, like a pendulum passing from one side to the other of the vertical line which is its quiescent position. Each of these oscillations is performed in a given thickness $2e$, twice as great as that in which the molecule had made its excursion in one direction. *Thus, from the thickness zero to a certain fundamental thickness* e', *the homogeneous molecules of which the ray passing through the crystal is composed, are affected, after their emergence, as if they had not quitted their primitive polarisation; from* e' *to* $2e$ *they are affected as if they had assumed a new polarisation, differing from the former by the azimuth* $2i$; i *being the angle which the principal section of the plate forms with the original plane of their polarisation;* and they appear, in short, alternatively polarised in their former azimuth, and in an azimuth at the distance $2i$ from it."

To this law it may be objected, first, that whenever the light emerging from a crystal with one axis, whether thin or thick, is composed of two distinct pencils, we find that they are polarised in directions at right angles to each other, whether the incident light may have been natural or polarised; and no exception to this rule has yet been discovered. Now it is difficult, if not impossible, to conceive, in the system of moveable polarisation, how the transition can be made from that state into the state of polarisation in two directions at right angles, which, for the sake of distinction, has been called the fixed polarisation.

But there is a still more direct objection to this theory. If we place a plate of sulphate of lime in such a manner that its principal section may make an angle of 45° with the primitive plane of polarisation of homogeneous light that is to pass through it, the angle $2i$ being then equal to 90°, the transmitted pencil, according to the doctrine of moveable polarisation, *would be* ENTIRELY *polarised either in the primitive plane or in the plane perpendicular to it,* and, when analysed by means of a rhomboid, it would exhibit, in two positions of the principal section of this crystal, only a single image. But this is so far from being true, that *if the plate is of a proper thickness*, the pencil will be constantly divided into two images of equal intensities, whatever the direction of the principal section of the rhomboid may be.

When two pencils, derived from the same origin, and possessing the same velocity, are made to intersect each other at a very small angle, after having travelled by different paths, of which the lengths are slightly different, they may destroy each other completely, as we have already seen; and this destruction would as readily take place if they came by the same path with different velocities. Let d be the difference of the paths which determines, in the first case, the periodical series of the points of space in which two rays of a certain homogeneous light produce complete darkness by their interference; the same letter d will express, in the second case, the quantity by which one of the rays will require to be more advanced than the other by the excess of its velocity, in order that the light may again be destroyed. When, in a crystallized plate, the difference of the tracks described by the ordinary and extraordinary rays of a given kind of light, or when the effect of the difference of velocity is 0, nd, or $(n + \frac{1}{2})d$, n being a whole number, a pencil previously polarised, and transmitted by the plate, WILL APPEAR *entirely polarised in the primitive plane, or in the azimuth* $2i$, as the principles of the doctrine of moveable polarisation require.

When the plate has such a thickness that the difference of the paths described by the ordinary and extraordinary pencils is included in the general formula $(n + \frac{1}{4})\,d$, the *transmitted light will appear to have become common light,* if the principal section of the plate makes an angle of 45° with the primitive plane of polarisation of the incident light, which, as we have already seen, by no means agrees with the doctrine of moveable polarisation.

Lastly, when the thickness of the plate employed is not comprehended in any of the preceding expressions, *the completely polarised rays, which pass through it, emerge with the characters of a partial polarisation.* This result is no less inconsistent than the former with the laws of moveable polarisation; since, according to these laws, the polarised incident ray ought always to emerge completely polarised, with a simple change of the azimuth of its poles.

It is not, therefore, generally true, that a pencil of polarised homogeneous light, which passes through thin crystallized plates, either preserves its primitive polarisation, or assumes a new one at the angular distance of $2i$; and with this falls the whole fabric of the oscillatory motions attributed to the molecules of light. With respect to the objection already made to this theory, regarding the connection to be established between the phenomena of thin plates and those of thick crystals, it seems to retain its full force, since it has not been established by experiment that the rays concerned in the phenomena of thin plates are polarised in two rectangular directions.

Supposing, however, for a moment, that this were the case, and that a luminous pencil, passing through a thin plate of sulphate of lime, is divided into two rays, the one ordinary and the other extraordinary, polarised at right angles: let us examine what would be the consequence. Mathematically speaking, these two rays follow in general different routes within the crystal; but it is not possible to separate them physically, because the imperfection of our organs forces us to contemplate objects of a certain extent. The advocates of a moveable polarisation will examine this light *in a mass.* They will find in certain cases that it appears to have preserved its primitive polarisation, and in others that it seems to be polarised in an azimuth differing by $2i$, and they will hence conclude that thin plates act very differently from a thick crystal.

This conclusion, however, may be disputed. When we make use of a thick crystal, the ordinary and extraordinary images are separated; we study the properties of each apart. In the case of the thin plates the observer has to do with light which is mixed and complicated. Now, who can affirm, without having made the experiment, that two rays really polarised at right angles, will not seem, in cases of interference, to have lost their primitive polarisations, and will not exhibit an intermediate polarisation, the *result* of the others, which might be considered as *composing* it?

The reader will now have conjectured, that, in order to elucidate these mysterious phenomena, it will require to be proved, first, that two pencils are actually formed in the thin plates of crystallized substances, as well as in thicker crystals, polarised at right angles to each other; and, secondly, that these pencils, when they are mixed, may exhibit the *appearance* of a polarisation intermediate between the two separate directions. Such, then, is the object of the very delicate experiments which are now to be related.

A pencil of homogeneous solar light being concentrated into a very small point, by the aid of a lens of a short focus, fixed in the shutter of a dark room, the pencil of diverging rays is to be received on two plates of glass slightly inclined to each other, and making an angle with the ray of about 35°: the pencils reflected by the two plates will then be completely polarised, and where they intersect each other they will form light and dark stripes; and whatever the position of the plates may be, the stripes will be polarised in the same direction as the two pencils which afford them.

If we now take a very transparent plate of sulphate of lime, and divide it in the middle, so as to have two plates of exactly the same thickness; if we fix one of the halves of this plate before the mirror, in such a situation that it may transmit that pencil only which is reflected by the first mirror, and so that the principal section may make an angle of 45° with the primitive plane of polarisation; and then the other half of the plate in the way of the polarised light reflected by the other mirror, but with its principal section at right angles to that of the other plate, and making an angle of 45° with the primitive plane in a contrary direction: *then, if these plates act in the same manner as thick plates*, however small the measure of their double refraction may be, they must divide the reflected rays which pass through them into two pencils of the same intensity, and polarised at right angles to each other; but, in the positions here assigned to them, it will evidently happen, that the plane of polarisation of the ordinary pencil, coming, for example, from the right-hand plate, will be parallel to the plane of polarisation of the extraordinary pencil of the left-hand plate; and the same will be true of the two remaining pencils of the respective plates.

This being admitted, it is easy to see what will happen at the points in which the two pencils intersect each other. The ordinary rays of the right-hand plate will at once interfere with the extraordinary rays of the left-hand plate, since they are polarised in the same direction, and will form a group of light and dark stripes; and a second group will be afforded by the extraordinary rays of the right-hand plate and the ordinary of its companion. The two groups will be the farther separated from each other as the plates are thicker, and as their double refraction is more strongly marked. In the intermediate space we find the rays of the same description furnished by the two plates; but as they have now received contrary polarities, they intersect each other without exhibiting any of the phenomena of interference, and the eye has the sensation of a uniform light only.

A fact which is no less evident than the existence of the two systems of stripes, is, that when we employ the sulphate of lime, each of the systems is completely polarised in a plane perpendicular to the principal section of the plate which is nearest to it.

Now, there is no one of the consequences of the supposition with which we set out, that is, the supposition that every plate divides polarised light passing through it *into two pencils polarised at right angles*, that is not fully confirmed by this experiment. The truth of the hypothesis is therefore demonstrated; for every other mode of separation or of polarisation of the rays, that for example which is deduced from the principles of moveable polarisation, would lead to phenomena totally different from those which have been described.

A little attention to the passages (Sect. VII.) containing an account of the circumstances under which polarised rays are capable of occasioning appreciable effects of interference, will be sufficient to convince the reader that the two systems of stripes which have been the subjects of these experiments, can only have been the result of the interference of the ordinary rays of one plate with the extraordinary rays of the other. But if any doubts were entertained on this subject, they might be removed in the following manner.

We might substitute for the two thin plates which have been employed, two thick crystals, for example two rhomboids of carbonate of lime, in which the double refraction would be manifest. As we might then follow separately the course of each pencil, and intercept them in turn by screens, it might thus be proved, by the most direct evidence, that, for the formation of the two groups of stripes, it is necessary and sufficient that the ordinary pencil of one of the crystals should meet the extraordinary pencil of the other, and the reverse. The direction of the polarisation of these fringes, determined by the aid of a rhomboid, would also be exactly the same as in the case of the employment of thin plates. The only remarkable difference between the two experiments would be in the degree of separation of the two groups of fringes. This distance, depending on the difference of the paths described by the ordinary and extraordinary rays, would be " greater" [or rather smaller] with the crystals than with the plates. It might even happen, if the crystals were very thick, that in order to " bring the stripes within the field of view" [or to render them visible], it would be necessary to compensate for a part of the difference of the lengths of the paths, or of the velocities, by the assistance of a plane glass, fixed in the way of one of the pencils; but in every case the results of the experiment would be equally clear and decisive.

It may also be added, in the last place, as a full answer to every objection that might be raised against this explanation of the formation of the two groups of stripes in the thin plates, that the interval which separates the two systems is always so dependent on the double refraction of the plates, that its exact numerical value may always be deduced from the elements of the double refraction, as obtained by experiments on other portions of the same substance. (See the article CHROMATICS.)

We must now consider how it will be possible to reconcile the experiment which has been related, and which proves the subdivision of the light into two pencils, polarised at right angles to each other, with the other fact, which seems to be opposed to it, that when the plate is of a proper thickness, the whole group of polarised rays that pass through it shall appear to be polarised either in the primitive plane or in another making with it an angle of $2i$.

We make, in a dark room, a very small radiant point of homogeneous light, by means of a lens, as already mentioned. We receive the diverging pencil on a plate of glass, having its posterior surface covered with a black varnish; supposing the plate to be in a vertical position, and the diverging pencil to be nearly horizontal, and to make an angle with the surface not much differing from that of complete polarisation: when this arrangement is completed, we place in the way of the reflected light a rhomboid of calcareous spar, its principal section making with the horizon, or with the plane of reflection, an angle of 45°. In this position of the rhomboid the light passing through it is divided into two pencils, the one ordinary and the other extraordinary, polarised at right angles, and of equal intensity. After having passed through the first rhomboid, the two pencils fall on another rhomboid of the same thickness, but having its principal section perpendicular to that of the former. The ordinary pencil will then be subjected to the extraordinary refraction in it, and the reverse; and the two pencils will emerge from the second rhomboid, one polarised in the plane of its principal section, and the other perpendicularly to it.

Let us now follow the course of each of the pencils. In the first place, it is evident, that on account of their divergence they will intersect each other in a space so much the wider as they become more remote from the rhomboid: their points of emergence being distinct and sensibly separated, the observer may intercept, in turn, with a screen, either the ordinary or the extraordinary pencil, and enlighten at pleasure any other object, either with the one or the other separately, or with both at once.

This delicate and complicated experiment being so far advanced, let us place a glass slightly roughened in a part of the field of view common to the two pencils; marking, by a very fine opening in an opaque plate covering the glass, the precise spot on which we fix our attention; and employing, as usual, a doubly-refracting crystal to analyse the different kinds of light, which, after passing through the slit in the diaphragm, depict an image within the eye.

It will now easily be observed that the ordinary ray, when it arrives alone at the aperture, wherever it may be placed, undergoes no modification, and remains polarised as it was before; and the same is true of the extraordinary ray: but if both these rays intersect each other in the slit, and enter the eye together, the phenomenon is by no means so simple, and its nature changes according to the place occupied by the slit; so that moving this slit gradually by means of a screw, we soon find the point where the light, composed of the two pencils that pass through it, seems to be wholly polarised, in the same manner as the pencil was at its first reflection from the plate of glass; further on, the plane of polarisation seems to be perpendicular to the primitive plane; and in a position intermediate between these the rays transmitted afford no material traces of polarisation at all.

This experiment, therefore, offers us the singular phenomenon of two pencils, polarised at right angles, which, after having intersected each other in the ground glass, unite within the eye, and form together, as the test of the rhomboid shows, a pencil polarised sometimes in one direction and sometimes in an opposite one, or sometimes without any sensible trace of polarisation, according to the magnitude of the difference of the paths described by the two pencils.

It is only to assist the imagination that the piece of ground glass has been supposed to be employed, for its presence is not necessary to the success of the experiment. A lens alone may be used for observing the stripes formed in the air by the interference of the luminous pencils. If, however, we merely placed ourselves with this lens before the two rhomboids, the eye would only receive a uniform and continued light; but as soon as a doubling crystal is perfectly *interposed* between the lens and the rhomboids, or between the lens and the eye, we shall observe two systems of dark and bright stripes, the bright stripes of one of the images corresponding always with the dark stripes of the other. The middle stripes, for example, will be bright in the ordinary image, *if the principal section of the interposed crystal is parallel to the primitive polarisation of the rays on the blackened glass;* and in the same case the middle stripe will be dark in the extraordinary image. The point of space occupied by the middle of the image seems therefore to transmit to the eye, through the crystal, only such light as is polarised in the primitive plane, because it affords only an ordinary image of the light; and this circumstance shows also that the effects of interference in the extraordinary image require, for their computation, the addition of $\frac{1}{2}d$ to the difference of the paths described.

When the principal section of the crystal interposed between the eye and the rhomboid is perpendicular to the original plane of polarisation, the two kinds of pencils interchange their effects; and in this case the central stripe of the ordinary image is bright, and that of the extraordinary image is completely dark, as if the difference of the paths of the rays forming it were $\frac{1}{2}d$.

It has been hitherto supposed that the original pencil contained only homogeneous light, so that it produced only bright and dark stripes. But if we employ white light, the stripes will be coloured; because d has different values for the rays of different tints, and these tints are precisely the same as are developed by polarised light in their passage through crystallized plates of all possible thicknesses.

A few words will now be sufficient to show the mode of action of these plates in the phenomena of the colours first described.

A polarised ray passing through a crystallized plate which possesses the power of double refraction is divided by it, mathematically speaking, into two pencils polarised at right angles; but two pencils of this description do not interfere; the plate will therefore not exhibit colours to the naked eye, whatever its thickness may be, even when it is only exposed to polarised light; and this result is confirmed by experiment.

Each of the ordinary and extraordinary pencils transmitted by the plate will again be divided into two when it passes through an achromatic prism of crystal, or a rhomboid of calcareous spar. Of these four emergent pencils, the two which follow the ordinary path will be no more separated than they were at their emergence from the plate; and the same is true of the two extraordinary pencils, so that the eye will ultimately perceive but two distinct images.

Of the two pencils which thus concur in the formation of the ordinary image, the one was ordinary in its passage through the plate, and has remained ordinary in the rhomboid placed near the eye, while the action of this rhomboid has been required for bringing the other pencil from the extraordinary to the ordinary refraction. The different kinds of rays have different velocities in crystals capable of double refraction; and an inequality of velocity gives rise to the phenomena of interference, as well as an inequality of distance described. If, in the plate employed, the difference between the velocities of the ordinary and extraordinary ray corresponds, either on account of its thickness or of the diversity of the two refractions, to a certain quantity, d, or its multiple, the kind of rays of which the interval nd determines the destruction, n being a whole number, will be wanting in the ordinary image transmitted by the rhomboid. And this effect, it must again be repeated, depends on the interference of the two pencils of which this image is really formed, and which, *in the plate*, possessed different velocities.

If the experiment with the two rhomboids had not taught us, that, in order to calculate the mutual actions of the luminous rays, which in passing through different crystals possessed of doubly refractive powers, have several times changed their planes of polarisation, the ordinary laws of interference require some modification, we should have found ourselves arrested by a considerable difficulty.

The difference of the velocities being the same for the two pencils of which the extraordinary image afforded by the rhomboid consists, and for the two which concur in the formation of the ordinary image, it would seem that the rays of the same colour ought to be destroyed at once in both the images, and that they ought to exhibit the same tint; but if we recollect that, after having calculated for one of the images the effect of interference corresponding to the difference d in the path, we are obliged, when we proceed to the other image, in order to obtain results conformable to experiment, to add $\frac{1}{2}d$ to the difference of the paths, or to the effect of the difference of the velocities, this difficulty will disappear. Supposing "d" [nd] in the ordinary image to occasion the destruction of the red rays, "$d + \frac{1}{2}d$" [$nd + \frac{1}{2}d$] will correspond, on the contrary, to their most complete agreement in the extraordinary image, and these two images will exhibit tints rigorously complementary to each other, as the experiment shows.

The colours developed by polarised light, in passing through crystallized plates being only, to speak correctly, portions of stripes produced by interference, we must expect to find in them, by varying the thicknesses of the plates, the same apparent deviations of the planes of polarisation as we found in the experiment on the narrow stripes produced by means of the rays transmitted by two plates of sulphate of lime, of which the principal sections were perpendicular to each other; and it has already been remarked that this analogy is supported by observation.

It can scarcely be doubted that this explanation will readily be adopted as fully satisfactory, by all those who will give themselves the trouble to examine it with sufficient attention; and the subject may now be concluded with the formulas which express the intensities of the ordinary and extraordinary images for the case of a polarised ray which has passed through one or two crystallized plates, with a perpendicular incidence, whatever may be the situation of their principal sections.

For a single plate, making unity the intensity of the primitive homogeneous pencil; i the angle made by the principal section of the plate with the primitive plane of polarisation; s the angle made by this same plane with the principal section of the rhomboid or of the achromatic prism, by means of which we analyse the emergent light; $o-e$ the difference of the paths of the ordinary and extraordinary rays at their emergence; d the interval already explained; and π the circumference of the circle of which the diameter is unity: we shall then have,

for the ordinary image, $\cos.^2 s - \sin. 2i \sin. 2(i-s) \sin.^2 \pi . \frac{o-e}{d}$;

for the extraordinary image, $\sin.^2 s + \sin. 2i \sin. 2(i-s) \sin.^2 \pi . \frac{o-e}{d}$.

When the polarised pencil has passed through two plates, there must be an additional element in the formula, that is, the angle formed by the principal section of this second plate with the primitive plane of polarisation. Let this angle be t, all the others retaining the same symbols, and let $o'-e'$ be the difference of the paths belonging to the second plate; the intensity of the ordinary image afforded by a pencil of homogeneous light will then be represented by

$$\cos.^2 s + \sin. 2t \sin. 2i \cos. 2(t+i-s) \sin.^2 \pi \frac{o-e}{d} - \sin. 2t \cos. 2i \sin. 2(t+i-s) \sin.^2 \pi \frac{o'-e'}{d} - \cos.^2 t \sin. 2i \sin. 2(t+i-s) \sin.^2 \pi . \frac{o-e+o'-e'}{d} + \sin.^2 t \sin. 2i \sin. 2(t+i-s) \sin.^2 \pi . \frac{o-e-(o'-e')}{d};$$

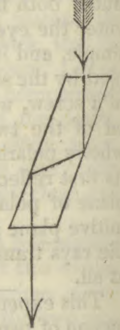
and the intensity of the extraordinary image is found by subtracting this expression from unity.

If we calculate separately, according to these formulas, the intensities of the rays of the different colours which compose white light, we obtain the *tint* of the ordinary or of the extraordinary pencil, whether the light, previously polarised, has passed through one or two crystallized plates; and if, in this calculation, we employ for $o-e$ and for $o'-e'$ the values corresponding to the *individual* double refractions to which the different species of rays are subject, we shall find the *most perfect agreement* between the formulas and the experiments, even in those crystals which afford tints that appear to bear *no resemblance* to those of the coloured rings of Newton.

The phenomena of these thin plates, therefore, which seemed to some persons to afford an unexceptionable demonstration of the system of emission; which seemed to require the assistance of the most singular oscillations of the molecules of light; which seemed to enable them to discover, in those particles, an axis of rotation, a pair of poles, and an equator; and even a kind of precession of the equinoctial points: these phenomena are in fact only, as we have just seen, the immediate and unavoidable consequences of the simple but inexhaustible laws of interference.

SECT. X.—ON CIRCULAR POLARISATION.[1]

The kind of polarisation which is now to be considered differs essentially from those which have been hitherto examined.



Suppose that, having polarised a pencil of light, we cause it to undergo twice over, at the angle of 54°, a total reflection within a parallelopiped of glass, as seen in the figure; the new planes of reflection being also supposed to be inclined at an angle of 45° to the plane of primitive polarisation; the emergent pencil will then have acquired some particular properties, which are very remarkable.

When this emergent pencil is analysed with a rhomboidal crystal, it is *constantly* decomposed into two rays of the same intensity, whatever may be the direction of the principal section. From this circumstance it might be supposed that it had resumed the character of ordinary light; but if it be transmitted through a crystallized plate before it is subjected to the action of the rhomboid, we shall soon perceive a distinction: for, in this case, common white light would afford two white images of the same intensity, while the light of the parallelopiped is divided into two pencils, both strongly coloured.

This new kind of rays has also some other peculiarities. It has already been remarked (Sect. V.), that one or more total reflections make no difference in the properties of ordinary light; but they modify, on the contrary, in a remarkable manner, the pencil which has passed through the parallelopiped: for this pencil resumes all the qualities of polarised light when it has been subjected to two total reflections similar to the first, whatever may be the azimuth of the latter planes of reflection with regard to the former.

The pencil of light in question is decomposed, then, into two coloured images, when it is only analysed by a rhomboid after having been transmitted through a crystallized plate; but it must be remarked, that the colour of each of these images, on the chromatic circle of Newton, is about one fourth of the circumference distant from the place which the colour of the same image would have occupied if we had employed only common polarised light.

It may also be added, as another distinguishing character, that this last kind of light gives rise to no phenomena of colour after being transmitted through plates of rock-crystal perpendicular to the axis, or through columns of oil of turpentine, or of other essential oils.

A polarised ray, modified by two total reflections, has therefore some very particular characters, which distinguish it equally from a direct ray and from an ordinary polarised ray; and as these characters have no relation to the different sides of the ray, the modification thus obtained has received the name of *circular polarisation*. If any person should think the denomination too little supported by the facts described, he may be informed, that it has been partly derived from some theoretical considerations, which appear to justify it.

---

[1] See the article OPTICS, p. 501.

The mode of obtaining the circular from the ordinary polarisation by means of two total reflections having been described, there remains to be mentioned a very remarkable method of procuring the circular polarisation more immediately from common light.

We cut out of a column of rock-crystal a very obtuse prism, with its two faces forming an angle of about 150°, and equally inclined to the axis of the column, and we make it achromatic as well as we can, with two prisms of glass cemented to its opposite faces: or, since this method must always be imperfect, we employ, instead of the glass, two other prisms of rock-crystal, taken from pieces which possess the opposite qualities which have been described in speaking of plagiedral crystals; and this arrangement has also the advantage of a separation of the images to a double distance. We obtain by means of this little combination the effects of double refraction; but the two pencils to which it gives birth, when they have been transmitted in a direction parallel to the axis of the column, have not acquired the same modification which Iceland spar, for example, would produce in them, but they are *circularly* polarised. Thus, if we analyse them with a rhomboid, they are always divided into two pencils of equal intensity; and when they have undergone two total reflections within a parallelopiped of glass at an angle of incidence of 54°, they are found completely polarised in two planes inclined 45° to the plane of reflection, the plane of polarisation of the one being to the right, and that of the other to the left.

There exists, therefore, a particular kind of double refraction, which communicates to the rays of light a circular polarisation, as the double refraction of the Iceland crystal produces in them the ordinary polarisation.

It follows, besides, from all the phenomena of this class, and from the general laws of interference, that a pencil circularly polarised may be considered as composed of two ordinary pencils polarised at right angles, one of them, however, being supposed to be retarded in its path, in comparison with the other, by a quarter of the interval which has been already noted by *d*.

The properties of rays circularly polarised afford us a very curious mode of reproducing exactly all the phenomena of colours, that we have observed in the plates of rock-crystal cut perpendicularly to the axis, and in certain liquids.

For this purpose we must place a thin crystallized plate between two parallelopipeds of ordinary glass crossed at right angles, and similar to that which has been already represented by a figure. A pencil, passing perpendicularly through the first parallelopiped, undergoes within it two total reflections at the angle of 54°; after its emersion, it is transmitted by the crystallized plate, and further on it enters the second parallelopiped, and is again twice reflected within it, but in a plane perpendicular to that of the former reflections: at last it emerges into the air, perpendicularly to the last surface of the parallelopiped. Now we may always obtain, in the emergent ray, the appearances of a polarised ray which passed through a plate of rock-crystal cut perpendicularly to the axis, or a certain depth of the essential oil of turpentine; and it will be sufficient for this purpose, that the pencil incident upon the first parallelopiped should be previously polarised, and that the axis of the interposed crystalline plate should make an angle of 45° with the two planes of the total reflections.

[SECT. XI.—ENUMERATION OF THE PRINCIPAL MINERALS WHICH ARE POSSESSED OF PARTICULAR PROPERTIES WITH RESPECT TO POLARISATION. ADDED BY THE TRANSLATOR.[1]

i. All such regular crystals as belong to the rhomboidal or pyramidal systems of crystallization, described by Mohs, are found to have one axis of double refraction, coincident with the crystallographic axis of these solids.—(Edinburgh Encyclopædia, article OPTICS, p. 572.) The axis of a refraction governed by the law of the *oblate* spheroid is called by Sir David Brewster a *negative axis*, by M. Biot a *repulsive axis*, and the axis of the oblong spheroid a *positive* or an *attractive* axis; the crystals are distinguished by the signs — and + respectively.

1. Rhomboid with obtuse summit.

— Carbonate of lime.
— Carbonate of lime and magnesia.
— Rubellite.
+ Dioptase.
— Carbonate of lime and iron.
— Tourmaline.
Ruby silver.

2. Rhomboid with acute summit.

— Corundum.
— Sapphire.
— Ruby.
Cinnabar.

3. Regular hexaedral prism.

— Emerald.
— Beryl.
— Phosphate of lime.
— Nepheline, or Sommite.
— Arseniate of copper.
— Arseniate of lead.

4. Octaedron with a square base.

+ *Z*ircon.
+ Oxyd of tin.
+ Tungstate of lime.
— Mellite.
— Molybdate of lead.
— Octohedrite.

5. Right prism with a square base.

+ Titanite.
— Idocrase.
— Wernerite.
— Meionite.
Uranite.

6. Bipyramidal dodecaedron.

+ Quartz.
— Phosphate of lead.
— Phosphato-arseniate of lead.

ii. Besides the erystals belonging to these classes, there are others of which the primitive form has not been determined, but in which the position of the single axis of double refraction has been ascertained.

Crystals.	*Axis of Double Refraction.*
— Mica from Kariat.	Perpendicular to the laminæ.
— Mica with amianthus.	Perpendicular to the laminæ.
— Hydret of strontia.	Perpendicular to the quadrangular plate.
— Arseniate of potass.	Axis of quadrangular prism.
— Muriate of lime.	Axis of hexaedral prism.
— Muriate of strontia.	Axis of hexaedral prism.
— Nitrate of soda.	Axis of obtuse rhomb.
— Subphosphate of potass.	Axis of quadrangular prism.
— Sulphate of nickel and copper.	Axis of quadrangular prism.
— Hyposulphate of lime (*Herschel*).	Axis of hexagonal tables.
+ Boracite.	Axis of cubical rhomb.
+ Apophyllite from Uton.	Axis of prism.
+ Apophyllite surcomposée.	Perpendicular to the plate.
+ Sulphate of potass and iron.	Axis of hexaedral prism.
+ Superacetate of copper and lime.	Axis of prism.
+ Hydrate of magnesia.	Perpendicular to the laminæ.
+ Ice.	Axis of hexaedral prism or rhomb.

iii. The crystals which have been enumerated appear to be symmetrical with respect to a single axis, so as to have similar properties in every plane passing through that axis; but Sir David Brewster discovered, in 1816, that in a great multitude of crystals the refractive powers are different in different planes passing through the principal axis; the phenomena and the laws of refraction being such as may be explained from the combined effects of two axes perpendicular to each other, and unequal in the ellipticity of the spheroids to which they belong.

---

[1] See the article OPTICS, p. 457.

"All regular crystals which belong to the *primitive* system of Mohs, or whose primitive forms are the *right prism*, with its base a rectangle, a rhomb, or an oblique parallelogram; the *oblique prism*, with its base a rectangle, a rhomb, or an oblique parallelogram; or the *rectangular and rhomboidal octaedron;* have *two* axes of double refraction, coincident with some permanent line in the primitive form."

1. Thus, all the combinations of the sulphuric, tartaric, and acetic acids, with single earthy, metallic, and alkaline bases, have two axes of double refraction.

2. The two *apparent* axes of crystals with two axes [or the lines in which the double refraction seems to be neutralised] have no symmetrical relation either with the faces or prominent lines of the primitive or secondary forms of minerals.

3. The two *rectangular* axes, the principal one of which is in the same plane with the two apparent axes, and *equidistant* from them, have a constant symmetrical relation to the faces and axes of the primitive forms in which they crystallize.

4. The line exhibited at any point of the sphere, by the joint properties of two axes, is represented by the diagonal of a parallelogram, of which the sides correspond to the tints belonging to the separate axes, and make with each other an angle twice as great as the angle formed by the planes passing through the given point and the two axes; and the increment or decrement of the square of the velocity of the light may be computed in the same manner as this line representing the tint.

iv. The necessity of any very minute investigation of the properties of particular substances, with regard to double refraction, is in great measure superseded by the very important facts, first observed by Sir David Brewster in 1814 and 1815, relating to the effects of heat and compression in producing double refraction and polarisation. He found that compression was capable of producing colour when a soft animal jelly was only touched by the finger; and that when a "negative" crystal, like that of the carbonate of lime, is compressed in the direction of the axis, the tints that it affords "descend," and that they "rise" when it is dilated: whence it seems to follow, that simple dilatation of a homogeneous substance in a given line will constitute that line the axis of an oblate spheriod; but the results require to be distinguished by a greater variety of experiments. M. Fresnel has succeeded in exhibiting not only colours by a strong pressure, but a very manifest reduplication of the image of a line, seen through a piece of glass strongly compressed by screws; and he performed this experiment very successfully at a meeting of the Parisian Academy of Sciences in 1822.]

SECT. XII.—HISTORICAL DETAILS RESPECTING THE DISCOVERY OF THE DIFFERENT PROPERTIES OF LIGHT CONCERNED IN POLARISATION.

It will now be necessary to enumerate the natural philosophers to whom we are indebted for the discoveries of which the importance has been explained in this article; and it will be convenient to do this in the order of the sections.

i. Huygens appears to be the first person that observed, in the two pencils derived from a single one, by means of double refraction, the existence of particular properties after their passage through the crystal, which they did not possess when they entered it. "It seems," he says, "that we are obliged to conclude, that the undulations of light, by passing through the first crystal of Iceland spar, acquire a certain form, or a certain disposition, by which, when they fall on the substance of a second crystal, in a certain position, they are enabled to affect both the kinds of matter which serve for the two species of refraction; and when they fall on it in another position, they only act on one of these substances."

Thus, according to this great philosopher, in the act of double refraction, the undulation, or the ray, changes its *form*, and loses its symmetry, so as to give room for the distinction of its different *sides*, or, changing the expression only, its different *poles*.

Huygens is therefore the first that observed a phenomenon of polarisation, and this discovery was made in 1678, though it was not published till 1690. From the time of Huygens to the year 1809, no observer, with the exception of the immortal author of the *Opticks*, had studied the subject of double refraction in this point of view; and it must even be acknowledged that, with respect to the facts in question, nothing was added by Newton to what the Dutch mathematician had discovered. He only insisted much more strongly on the necessity of admitting poles in each of the rays derived from the subdivision which light undergoes in passing through an Iceland crystal. To Malus belongs the honour of having brought back the attention of natural philosophers to the properties of light which form the subject of this article. It was he that first pointed out the singular phenomena exhibited by the ordinary and extraordinary rays when they meet with transparent reflecting surfaces at certain inclinations; and it is to him that we are indebted for the mathematical law which appears to connect intensities of the different pencils into which the light is divided when it passes through two rhomboids of the spar in succession.[1]

ii. The anecdote, which has been often told, of the fortunate circumstance that led Malus to the discovery of the polarisation of light by reflection from transparent substances, is perfectly correct. This philosopher, so early arrested in his pursuit of science by a premature death, and so universally lamented by his friends, has often related to the author of this article, that as he happened to be decomposing, by means of a rhomboid of carbonate of lime, towards the end of the year 1808, the light of the setting sun, reflected from the glass of the windows of the Luxembourg, he first observed the difference of the intensity of the two images in different positions of the rhomboid; but it is not true, as has sometimes been stated, that one of the images actually disappeared in this observation; for the polarisation of the light, at the moment of the experiment, was only partial. A similar difference of intensity must have been before the eyes of mineralogists whenever they had been trying to examine the double refraction of crystals, and had projected the needle which they used for an object of view on a clear and serene sky, which affords a curtain of polarised light. But the fact had not excited their attention. Malus observed it, was struck with all its importance, completely analysed it in all its forms, with the most singular sagacity, and thus became the creator of a new branch of optics. It is to this celebrated observer that we are indebted for all the experiments related in the second section.[2]

iii. The measurements related in the third section, which appear to show that, at equal angular distances above and below the angle of complete polarisation, the reflected rays contain nearly equal quantities of polarised light, were obtained by M. Arago.

[2] *Ibid.* ii.

iv. It was Sir David Brewster that discovered the remarkable law which connects the angle of complete polarisation with the refractive density of the substance. It was communicated to the Royal Society on the 16th March 1815.[1]

The relation of the angle of complete polarisation, at the second surface of a transparent medium, to the angle belonging to the first surface, had before been shown by Malus.[2] The same relation may be extended to the angles, at the same surfaces, which afford polarisation of *equal proportions* of the light falling on them. So that the rule given by Malus is only a particular case of a general theorem, which M. Arago has deduced from a long series of experiments that have not been published.

v. It was discovered also by Malus, that the pencil *transmitted* by a transparent plate is partially polarised in a plane at right angles to the plane of polarisation of the reflected pencil. This fact was communicated to the Institute on the 11th March 1811, and published the next day in the *Moniteur*. See also the Memoirs of the Mathematical Class for 1810. The photometrical experiments of M. Arago have established a relation between these two kinds of polarisation which had been unobserved by Malus; it is contained in this simple enunciation. "The quantity of polarised light contained in the pencil which any transparent plate transmits, is exactly equal to *the quantity* polarised in the contrary direction, which is found in the light reflected by the same plate." These experiments were made in 1812, but they were first published in 1814 by M. Biot, to whom M. Arago had communicated them.[3]

It follows from this law, as M. Arago had also observed, that at the angle of total reflection, and at all greater obliquities, the light wholly escapes polarisation.

The phenomena exhibited by piles of plates were analysed by Malus immediately after his discovery of polarisation by refraction.

The observation that some natural bodies, agates, for example, act on light precisely like these piles of plates, is due to Sir David Brewster.[4]

vi. The laws and experiments related in the sixth section belong to M. Fresnel. Malus had before attempted to discover in what manner the planes of polarisation changed their directions; but there are several inaccuracies in the results which he has published.[5] The formulæ of M. Fresnel are some of the most valuable additions that have been made of late to the science of optics. A general account of the deviations undergone, in reflection, by the plane of polarisation of a ray previously polarised, is found in two memoirs presented to the academy by M. Fresnel, on the 24th November 1817, and the beginning of January 1818; but the mathematical laws of the phenomena were not discovered and published till 1821.[6]

vii. M. Arago and M. Fresnel are hitherto the only philosophers who have examined the effect of polarisation in modifying the phenomena of interference. The memoir in which they first recorded the results which are inserted in the seventh section, appeared in the *Annales de Chimie* for 1819, vol. x.

viii. It was M. Arago that first observed the changes in the properties of polarised rays when they pass through crystalline plates. He showed that they acquire the property of being divided by calcareous spar into two coloured pencils, and of being reflected by transparent substances with tints which vary according to the angular position of their surfaces. His memoir was read to the Institute on the 11th of August 1811, and printed in the volume of the *Mémoires* of that year.

Sir David Brewster published some similar experiments in his Treatise on Philosophical Instruments, which appeared in 1813.

The phenomena exhibited by plates cut perpendicularly to the axis were also described by M. Arago in the same memoir.

We are indebted to M. Biot for the rule, according to which the deviation of the poles is effected, whether on account of the particular kind of "each luminar molecule," or on account of the more or less considerable thicknesses of the plates by which these "molecules" have been transmitted. His memoir was read to the Institute in September 1818, and printed shortly afterwards.

Mr Herschel is the author of the curious observation relating to the facets of plagiedral crystals.[7]

The extension of the properties of plates perpendicular to the axis, by which they are assigned to the strata of certain liquids, was made by M. Biot in 1815.[8]

ix. The laws of the depolarisation produced by crystallized plates, parallel to the axis, are reduced to the three following.

1. The motion of the plate in its plane does not alter the tints of the images furnished by a rhomboid. This result is implicitly comprehended in the first memoir of M. Arago; since in the description of all the motions which cause a change of the tints, the motion of the plate in its own plane is not included.

2. The tints of the two images are those of the coloured rings of Newton, seen by reflection or by transmission. This law had been laid down by M. Biot; but Mr Herschel has shown in the Cambridge Transactions that it is not universally true,[9] so that its theoretical importance is lost.

3. In a crystal of variable thickness, the same phenomena of polarisation are reproduced at thicknesses which form a series like that of the coloured rings of Newton. When we examine with a rhomboid a crystal cut in a proper manner, so that two of its faces form an angle, and which is projected on a back ground affording polarised light, each image appears bordered by regular streaks, parallel to the angular edge of the prism, and separated by equal spaces. M. Arago, when he described this phenomena in August 1811, advanced it as a sufficient proof of this third law. The Academy of Sciences, and M. Laplace in particular, did not admit the conclusion as demonstrated, and a direct admeasurement of the thicknesses was required. Count Rumford, who was present, offered the use of an instrument which he had employed for some other purposes, and which seemed to promise a sufficient degree of precision: the common comparer was also mentioned as proper for the purpose. M. Arago, upon these suggestions, undertook to make these further experiments. But M. Biot anticipated him; and he has *therefore* a claim to the *first direct demonstration* of the law of the thicknesses.

4. The brilliant tints of each of these images may be calculated from the laws of interference, according to the difference of the paths and of the velocities of the ordinary and extraordinary rays. This important remark is due to Dr Thomas Young, who is believed to have published it in the Quarterly Review, xi. 1814, p. 42–49.

It affords the true key of all these phenomena. It must however be added, that Dr Young had not explained either in what circumstances the interference of the rays can take place, nor why we see no colours unless the crystallized plates are exposed to light previously polarised. The new properties which required to be combined with the ordinary laws of interference, in order to obtain a *complete* explanation of the facts, were discovered by M. Arago and M. Fresnel, as they have been described in the seventh section. The dates of the memoirs in which M. Fresnel published this explanation are 1816 and 1818.

The ingenious and delicate experiments which have been employed as tests of the inaccuracy of the theory of moveable polarisation are also due to M. Fresnel, one of the most inventive theorists as well as one of the most skilful experimenters that have devoted themselves to science in this or in any age: the formulæ found at the end of the section are also M. Fresnel's.

x. The phenomena of circular polarisation were discovered by M. Fresnel, who described and analysed them in a memoir read to the Academy of Sciences in November 1817 and in January 1818. His later researches on this subject are inserted in the *Bulletin* of the Philomathic Society, December 1822 and February 1823.

There are a few other particulars, relating to the development of tints by repeated reflections at the surfaces of metallic mirrors,[1] to the rings seen in crystallized plates cut perpendicularly to the axis when examined with a rhomboid held very near them, and to the phenomena of the absorption of polarised light by certain crystals.[2] The first have hitherto been reduced to no *direct* analogy with other affections of polarised light; the second seem to be derived from a modification of the laws already explained in the ninth section; and the discovery of the scattered phenomena belonging to the third head has been disputed by M. Biot and Sir David Brewster, but they appear to have been first observed by M. Arago in 1814.[3]

[SECT. XIII.—THEORETICAL INVESTIGATIONS INTENDED TO ILLUSTRATE THE PHENOMENA OF POLARISATION. ADDED BY THE TRANSLATOR.

We are led, from the facts which have been enumerated in the eleventh section, to the remarkable coincidence between the discoveries of Sir David Brewster respecting crystals with two axes, and a theory which had been published a few years *earlier* in order to illustrate the propagation of an undulation in a medium compressed or dilated in a given direction only, and to prove that such an undulation must necessarily assume a spheroidal form, upon the mechanical principles of the Huygenian theory. As every contribution to the investigation of so difficult a subject may chance to be of some value, it will be worth while to copy this demonstration here, from the Quarterly Review for November 1809, vol. ii. p. 345.

"The proposition to be demonstrated was this: *An impulse is propagated through every perpendicular section of a lamellar elastic substance in the form of an elliptic undulation.*

"When a particle of the elastic medium is displaced in an oblique direction, the resistance produced by the compression is the joint result of the forces arising from the elasticity in the direction of the laminæ, and in a transverse direction; and if the elasticities in these two directions were equal, the joint result would remain proportional to the displacement of the particle, being expressed, as well in magnitude as in direction, by the diagonal of the parallelogram, of which the sides measure the relative displacements, reduced to their proper directions, and express the forces which are proportional to them. But when the elasticity is less in one direction than in the other, the corresponding side of the parallelogram expressing the forces must be diminished, in the ratio which we may call that of 1 to m; and the diagonal of the parallelogram will no longer coincide in direction with the line of actual displacement, so that the particle displaced will also produce a lateral pressure on the neighbouring particle of the medium, and will itself be urged by a lateral force. This force will, however, have no effect in promoting the direct propagation of the undulation, being probably employed in gradually changing the direction of the actual motions of the successive particles; and the only efficient force of elasticity will be that which acts in the direction in which the undulation is advancing, and which is expressed by the portion of the line of displacement, cut off by a perpendicular falling on it from the end of the diagonal of the parallelogram of forces; and the comparative elasticity will be measured by this portion, divided by the whole line of displacement. Calling the tangent of the angle formed by the line of displacement with the line of greatest elasticity t, the radius being 1, the force in this line being also 1, the transverse force will be expressed by mt, the line of displacement by $\surd(1+tt)$, its diminution by $\frac{(1-m)\,tt}{\surd(1+tt)}$, the diminished portion, which measures the force, by $\surd(1+tt)-\frac{(1-m)tt}{\surd(1+tt)}$, and the elasticity, in the given direction, by $\frac{1+mtt}{1+tt}$. Hence it follows, that the velocity of an impulse, moving in that direction, will be expressed by $\surd\frac{1+mtt}{1+tt}$.

"It is next to be proved, that the velocity of an elliptical undulation, increasing so as to remain always similar, by means of an impulse propagated always in a direction perpendicular to the circumference, is such as would take place in a medium thus constituted. It is obvious that the increment of each of the diameters of the increasing figure must be proportional to the whole diameter; and this increment, reduced to a direction perpendicular to the curve, will be proportional to the perpendicular falling on the conjugate diameter, which will measure the velocity. We are therefore to find an expression for this perpendicular when it forms an angle with the greater axis, of which the tangent is t. Let the greater semiaxis be 1, and the smaller n; then the tangent of the angle formed with the greater axis by the conjugate diameter being $\frac{1}{t}$, the tangent of the angle subtended by the corresponding ordinate of the circumscribing circle is found $\frac{1}{nt}$, and the semidiameter itself, equal to unity, reduced in the ratio of the secants of these angles, that is, to $n\surd\frac{1+tt}{1+nntt}$; but, by the known property of the ellipsis, the perpendicular required is equal to the product of the semiaxis, divided by this semidiameter, that is, to $\surd\frac{1+nntt}{1+tt}$; we have therefore only to make $nn=m$, and the velocity in the given medium will always be such as is required for the propagation of an undulation, preserving the form of similar and concentric spheroids, of which the given ellipsis represents any principal section.

"If the whole of the undulation were of equal force, this reasoning would be sufficient for determining its motion; but when one part of it is stronger than another, this superiority of pressure and motion will obviously be propagated in the direction of the actual resistance produced by the displacement of the particles, since it is this resistance which carries on the pressure, and consequently propagates the motion. It is very remarkable that the direction of the resistance will be found, on the supposition which has been advanced respecting the constitution of the medium, to coincide everywhere with the diameters of the ellipsis when the displacement is perpendicular to the surface. For it is proved by authors on conic sections, that the subnormal of the ellipsis is to the absciss as the square of the lesser axis is to the square of the greater, that is, in this case, as nn to 1, or as m to 1; but if we divide the ordinate to the same ratio of m to 1, and join the point of division with the extremity of the subnormal, this line, which will evidently be parallel to the diameter, will express, as we have already seen, the direction of the force when the normal represents that of the displacement. An immediate displacement in the direction of any diameter, making an angle with the axis of which the tangent is t, would give a velocity of $\sqrt{\frac{1+mtt}{1+tt}}$, while the increment of the diameter would require a velocity of $\sqrt{\frac{m+mtt}{m+tt}}$, which does not vary in the same proportion. It must, however, be remembered, that the rectilinear direction of the beam is not supposed to depend on this circumstance alone. Huygens considers each point of the surface of the crystal, on which a beam of light impinges, as the centre of a new undulation, which spreads in some measure in every direction, but produces no perceptible effect except where it is supported by, and co-operates with, the neighbouring undulations, that is, in the surface which is a common tangent of the collateral undulations; but if this principle were applied to extraordinary refraction without the assistance of the obliquity of force, which may be deduced from the supposition of a stratified medium, it would lead us to expect that the elementary impulses, being propagated in a curvilinear trajectory, might be intercepted by an object not situated in the rectilinear path of the beam; a conclusion which is not warranted by experiment."

---

However satisfactorily this mode of viewing the extraordinary refraction may be applied to the subsequent discoveries relating to the effects of heat and compression, there is another train of ideas, which arises more immediately from the phenomena of polarisation, and which might lead us to a more distinct notion of the separation of the pencil into two or more portions, though it does not seem to comprehend so entirely the phenomena depending on spheroidal undulations.

We may begin this mode of considering the subject in the words which have already been employed in the article CHROMATICS, vol. vi. p. 649. "If we assume as a mathematical, postulate, in the undulatory theory, without attempting to demonstrate its physical foundation, that a transverse motion may be propagated in a direct line, we may derive from this assumption a tolerable illustration of the subdivision of polarised light by reflection in an oblique plane. Supposing polarisation to depend on a transverse motion in the given plane; when a ray completely polarised is subjected to simple reflection in a different plane, at a surface which is destitute of any polarising action, and which may be said to afford a neutral reflection, the polar motion may be conceived to be reflected, as any other motion would be reflected, at a perfectly smooth surface, the new plane of the motion being always the image of the former plane; and the effect of refraction will be nearly of a similar nature. But when the surface exhibits a new polarising influence, and the beams of light are divided by it into two portions, the intensity of each may be calculated, by supposing the polar motion to be resolved instead of being reflected, the simple velocities of the two portions being as the cosines of the angles formed by the new planes of motion with the old, and the energies, which are the true measure of the intensity, as the squares of the sines. We are thus insensibly led to confound the intensity of the supposed polar motion with that of the reflected light itself; since it was observed by Malus, that the relative intensity of the two portions into which light is divided under such circumstances, is indicated by the proportion of the squares of the cosine and sine of the inclination of the planes of polarisation. The imaginary transverse motion might also necessarily be alternate; partly from the nature of a continuous medium, and partly from the observed fact, that there is no distinction between the polarisations produced by causes precisely opposed to each other in the same plane." Another analogous hint is found in the Philosophical Transactions for 1818, p. 273. "Supposing the experiments to be perfectly represented by [Dr Brewster's] general law, it will follow that the tint exhibited depends not on the difference of refractive densities in the direction of the ray transmitted, but on the greatest difference of refractive densities in directions perpendicular to that of the ray. These two conditions lead to the same result where the effect of one axis only is considered, but they vary materially where two axes are supposed to be combined...... There can be little doubt that the direction of the polarisation, in such cases, must be determined by that of the greatest and least of the refractive densities in question:" a "supposition" which Dr Brewster finds "quite correct."

We may add again to these hints the consideration, that when simple pressure or extension in the direction of any given axis produces a spheroidal undulation in a medium before homogeneous, this state is always accompanied by the condition, that a ray describing the axis, while the densities in all transverse directions remain equal, undergoes no subdivision; but that a ray moving in the plane of the equator, to which the perpendiculars are the axis and another equatorial diameter, undergoes the greatest possible separation into parts that are respectively polarised in the planes passing through these directions.

From these phenomena we are led to be strongly impressed with the analogy of the properties of sound, as investigated cursorily by Mr Wheatstone, and in a more elaborate manner by the multiplied experiments of M. Savart, which have shown that, in many cases, the elementary motions of the substances transmitting sound are transverse to the direction in which the sound is propagated, and that they remain in general parallel to the original impulse.

The next transition carries us from the *mathematical postulate* here mentioned, to the *physical condition* assumed by M. Fresnel, that the relative situation of the particles of the ethereal medium with respect to each other, is such as to produce an elastic force tending to bring back a line of particles which has been displaced, towards its original situation, by the resistance of the particles *surrounding the line*, and at the same time to impel these particles in its own direction, and in that direction only, or principally, while the aggregate effect is propagated in concentric surfaces.

This hypothesis of M. Fresnel is at least very ingenious, and may lead us to some satisfactory computations; but it is attended by one circumstance which is perfectly *appalling* in its consequences. The substances on which M. Savart made his experiments were *solids* only, and it is only to solids that such a *lateral* resistance has ever been attributed; so that if we adopted the distinctions laid down by the reviver of the undulatory system himself in his Lectures, it might be inferred that the luminiferous ether pervading all space, and penetrating almost all substances, is not only highly elastic, but absolutely solid. The passage in question is this:—

"The immediate cause of solidity, as distinguished from liquidity, is the lateral adhesion of the particles to each other, to which the degree of hardness or solidity is always proportional. This adhesion prevents any change of the relative situation of the particles, so that they cannot be withdrawn from their places, without experiencing a considerable resistance from the force of cohesion, while those of liquids may remain equally in contact with the neighbouring particles, notwithstanding their change of form. When a perfect solid is extended or compressed, the particles, being retained in their situations by the force of lateral adhesion, can only approach directly to each other, or be withdrawn farther from each other; and the resistance is nearly the same as if the same substance, in a fluid state, were enclosed in an unalterable vessel, and forcibly compressed or dilated. Thus the resistance of ice to extension or compression is found by experiment to differ very little from that of water contained in a vessel; and the same effect may be produced even when the solidity is not the most perfect that the substance admits; for the immediate resistance of iron or steel to flexure is the same, whether it may be harder or softer. It often happens, however, that the magnitude of the lateral adhesion is so much limited as to allow a capability of extension or compression, and it may yet retain a power of restoring the bodies to their original form by its re-action. This force may even be the principal or the only source of the body's elasticity. Thus, when a piece of elastic gum is extended, the mean distance of the particles is not materially increased...and the change of form is rather to be attributed to a displacement of the particles than to their separation to a greater distance from each other, and the resistance must be derived from the lateral adhesion only. Some other substances, also, approaching more nearly to the nature of liquids, may be extended to many times their original length, with a resistance continually increasing; and in such cases there can scarcely be any material changes of the specific gravity of these substances. Professor Robison has mentioned the juice of bryony as affording a remarkable instance of such viscidity.

"It is probable that the immediate cause of the lateral adhesion of solids is a symmetrical arrangement of their constituent parts. It is certain that almost all bodies are disposed, in becoming solid, to assume the form of crystals, which evidently indicates the existence of such an arrangement; and all the hardest bodies in nature are of a crystalline form. It appears, therefore, consistent both with reason and with experience to suppose, that a crystallization more or less perfect is the universal cause of solidity. We may imagine, that when the particles of matter are disposed without any order, they can afford no strong resistance to a motion in any direction; but when they are regularly placed in certain situations with respect to each other, any change of form must displace them in such a manner as to increase the distance of a whole rank at once; and hence they may be enabled to co-operate in resisting such a change. Any inequality of tension in a particular part of a solid is also probably so far the cause of hardness, as it tends to increase the strength of union of any part of a series of particles which must be displaced by a change of form."

It must, however, be admitted, that this passage by no means contains a demonstration of the total incapability of fluids to transmit any impressions by lateral adhesion, and the hypothesis remains completely open for discussion, notwithstanding the apparent difficulties attending it; which have appeared to bring us very near to the case stated in the same lectures as a possible one, that there may be independent worlds, some existing in different parts of space, others pervading each other unseen and unknown in the same space. We may perhaps accommodate the hypothesis of M. Fresnel to the phenomena of the ordinary and extraordinary refraction, by considering the undulations as propagated through the given medium in two different ways; some by the divergence of the elementary motions in the direction of the ray, and others by their remaining parallel to the direction of the impulse or of the polarisation. The former must be supposed to furnish the spheroidal, the latter the spherical refraction. It would indeed follow that the velocity of the spherical undulation ought to vary by innumerable degrees, within certain limits, according to the direction of the supposed elementary motion; whilst in fact the actual velocity of the spherical undulations seems to be uniformly equal to the velocity in the direction of the axis; but this objection may be obviated by supposing the surface so constituted, that for some unknown reason the parallel elementary motion can only be propagated in the regular manner when it takes place in the direction of the axis, or when it is made to assume that direction; a condition not very simple or natural, but by no means inconceivable, unless we saw any reason to consider the adhesion as a constant force, independent of the direction, and equal to the least or greatest elasticity, or unless it were possible to derive the phenomena of two supposed axes of polarisation, which M. Fresnel has explained on the hypothesis of two spheroids, from the supposition of two spherical undulations propagating oblique elementary motions in the direction of the actual polarisation, as already determined for these crystals.

If these conjectures should be found to afford a single step in an investigation so transcendently delicate, it will be best to pause on them for a time, and to wait for further aid from a new supply of experiments and observations.] (T. T. T. T.)

POL DE LEON, a city of France, in the department of Finisterre, and arrondissement of Morlaix. It is situated on a hill near the sea, about a mile from its haven Penpont, which is accessible to small vessels. It is the see of a bishop, and has a cathedral and other churches, 1005 houses, and 6150 inhabitants, who make linen goods, and some pottery ware. Long. 3. 53. 26. W. Lat. 48. 40. 55. N.

POLE, Reginald, cardinal, and archbishop of Canterbury, a younger son of Sir Richard Pole, Lord Montague, was born at Stoverton Castle, in Staffordshire, in the year 1500. At seven years of age he was sent to a Carthusian monastery at Shene, near Richmond, in Surrey; and thence, when he was about twelve years old, removed to Magdalen College, in Oxford, where, by the instruction of the celebrated Linacre and Latimer, he made considerable progress in learning. In 1515 he took the degree of bachelor of arts, and was admitted to deacon's orders some time afterwards; in 1517, he was made prebendary of Salisbury, and in 1519 dean of Wimborne and dean of Exeter. We are not surprised at this young nobleman's early preferments, when we consider him as the kinsman of Henry VIII. and that he was bred to the church by the king's special command.

Being now about the age of nineteen, he was sent, according to the fashion of the times, to finish his studies at Padua, in Italy, where he resided some time in great splendour, having a handsome pension from the king. In 1525 he returned to England, where he was most graciously received at court, and universally admired for his talents and address; but preferring study and sequestration to the pleasures of a court, he retired to the Carthusian convent at Shene, where he had continued about two years, when the pious king began to divulge his scruples of conscience concerning his marriage with Catharine of Spain. Pole foresaw that this affair would necessarily involve him in difficulties; he therefore determined to quit the kingdom, and accordingly obtained leave to visit Paris. Having thus avoided the storm for the present, he returned once more to his convent at Shene; but his tranquillity was again interrupted by the king's resolution to shake off the pope's supremacy, of which Pole's approbation was thought indispensably necessary. How he managed in this affair is not very clear. However, he obtained leave to revisit Italy, and his pension was continued for some time.

The king, having now divorced Queen Catharine, married Anne Boleyn; and being resolved to throw off the papal yoke, ordered Dr Richard Sampson to write a book in justification of his proceedings, which he sent to Pole for his opinion. To this Pole, secure in the pope's protection, wrote a vehement answer, entitled *Pro Unitate Ecclesiasica*, and sent it to the king, who was so much offended with the contents, that he withdrew his pension, stripped him of all his preferments, and procured an act of attainder to be passed against him. In the mean time, Pole was created a cardinal, and sent in quality of nuncio to different parts of Europe. Henry made several attempts to have him secured and brought to England, but all of them proved abortive. At length the pope fixed him as legate at Viterbo, where he continued till the year 1543, when he was appointed legate at the council of Trent, and was afterwards employed by the pope as his chief counsellor.

Pope Paul III. having died in 1540, Pole was twice elected his successor, and, we are told, twice refused the papal dignity; the first time, because the election was made in too great haste; and the second, because it was done in the night. Cardinal Maria de Monte obtained the triple crown; and Pole, having kissed his slipper, retired to the convent of Magazune, near Verona, where he continued till the death of Edward VI. in the year 1553. On the accession of Queen Mary, Pole was sent as legate to England, where he was received by her majesty with great veneration, and conducted to the archbishop's palace at Lambeth, Thomas Cranmer being at that time prisoner in the Tower. He immediately appeared in the House of Lords, where he made a long speech; and this being reported to the Commons by their speaker, both these houses concurred in an humble supplication to be reconciled to the see of Rome. They presented it on their knees to her majesty, who interceded with the cardinal, and he graciously condescended to give them absolution. This business being ended, the legate made his public entry into London, and immediately set about the extirpation of heresy. The day after the execution of Cranmer, which he is falsely said to have advised, he was consecrated archbishop of Canterbury. In the same year, 1556, he was elected chancellor of the university of Oxford, and soon afterwards of Cambridge; both which he visited, by his commissioners. He died of a double quartan ague, in the year 1558, about sixteen hours after the death of the queen, and was buried in the cathedral of Canterbury.

As to his character, the Catholic writers ascribe to him every virtue under heaven; and even Bishop Burnet is lavish in his praise, attributing the cruelties of Mary's reign to the advice of Gardiner. In this Mr Hume agrees with the bishop, and represents Pole as the advocate of toleration. By every impartial account, he seems to have been a man of mild manners and of real worth, though undoubtedly a zealous member of the church of Rome. He wrote, *Pro Unitate Ecclesiastica, De Ejusdem Potestate*, a Treatise on Justification, and various other tracts.

Pole, in *Astronomy*, that point in the heavens round which the whole sphere seems to turn. It is also used for a point directly perpendicular to the centre of the plane of any circle, and distant from it by the length of a radius.

Pole-Axe, a sort of hatchet, nearly resembling a battle-axe, and which is principally employed in sea-fights, to cut away and destroy the rigging of any adversary who endeavours to board.

POLEIN, in English antiquity, is a sort of shoe, sharp or piked at the point. This fashion took its rise in the time of William Rufus; and the pikes were so long that they were tied up to the knees with silver or golden chains. But they were forbidden by statute 4, Edward IV. cap. 7.

POLEMARCHUS, a magistrate at Athens, who had under his care all the strangers and sojourners in the city, over whom he had the same authority as the archon had over the citizens.

POLEMICAL, in matters of literature or theology, an appellation given to books of controversy.

POLEMO, who succeeded Xenocrates in the direction of the academy, was an Athenian of distinguished birth, but in the earlier part of his life a man of loose morals. The manner in which he was reclaimed from the pursuit of infamous pleasures, and brought under the discipline of philosophy, affords a memorable example of the power of eloquence employed in the cause of virtue. As he was, one morning about sunrise, returning home from the revels of the night, he passed by the school of Xenocrates, and saw him surrounded with his disciples. Unable to resist so fortunate an opportunity of indulging his sportive humour, he rushed without ceremony into the school, and took his place amongst the philosophers. The whole assembly was astonished at this intrusion, and all but Xenocrates discovered signs of resentment. Xenocrates, however, preserved perfect command of his temper, and turning his discourse from the subject on which he was treating to the topics of temperance and modesty, he recommended them with such strength of argument and energy of language, that Polemo was constrained to yield to the force of conviction. Instead of turning the philosopher and his doctrine to ridicule, as he at first intended, he became sensible of the folly of his former conduct; was heartily ashamed of the contemptible figure which he had made in so respectable an assembly; assumed a sedate and thoughtful aspect; and resolved from that hour to relinquish his licentious pleasures, and devote himself to the pursuit of wisdom.

POLESINA, a delegation of Austrian Italy, in the province of Milan. It is bounded on the north by Padua, on the east by Venice, on the south by the papal states, and on the west by Mantua and Verona. It is 434 square miles in extent, and contains 135,200 inhabitants. It is a level district, without woods; but abounding in lakes and morasses, which render it unhealthy. The district is enclosed by the rivers Po and Etsch; and the interior is drained by the Adigetto, Tartaro, Castognaro, and many canals. The soil is very fruitful, and yields abundantly of maize, oats, wheat, and rice; and also much fruit, hemp, flax, wine, and good silk. The soil likewise furnishes abundance of nitre, the preparation of which affords much employment. The only other manufactures are those of leather, bricks, and tiles. The capital is Rovigio. In the time of the Romans this district was a marsh, known as *Paludes Padusæ*. It is now divided into seven districts, which are subdivided into fifty-six communes.

POLETÆ were ten magistrates of Athens, who, with three that had the management of the money allowed for public shows, were empowered to let out the tribute-money and other public revenues, and to sell confiscated estates; all which transactions were ratified by their president, or in his name.

POLIANTHES, the Tuberose, a genus of plants belonging to the hexandria class; and in the natural method ranking under the tenth order, *Coronariæ*.

POLICE.

The word *Police* has two meanings. According to the first, it is the science of regulating whatever belongs to the internal economy of a state; according to the second, or limited meaning, it is merely a system of preventive justice.

General definition.

The first definition may appear so extensive, as to make it possible to confound the idea of the science of police with that of politics, or government, as defined by Aristotle to consist of the ordering of all things in the state towards the ultimate end, namely, the common happiness. But the distinction may be understood, by comparing the operation of police regulations in society, to that of a system of domestic order in a family. The members of a commonwealth, like those of a family, must conform their conduct to certain conventional rules, which the chief authority enforces amongst them, for their mutual advantage, in addition to the moral duties which belong to them in common with all men. A breach of an economical law of this description, is an offence against police. Thus, whilst an assault, or a theft, is an offence against the person, or property, of a citizen; treason, one against the sovereign power; or perjury, one against the administration of justice; vagrancy, gaming, bigamy, and the like, are understood to be offences against the public police, upon the ground that the tendency of such acts, without reference to the question of their immorality, is injurious to the economy of society.[1]

But it is the office of police, taken in a large sense, to go farther than forbidding certain injurious acts. It may employ indirect means to prevent the commission of crimes. It may seek to avert the will of the citizen from a breach of the law, by turning his inclinations into a direction conformable to the public interests. Thus, it may avoid the use of any punishment containing ingredients which might make it an object of desire; it may take all possible care that punishment shall be certain; it may cultivate religious sentiments in the people; it may instruct them in their moral and social duties, and provide them with the means of agreeable recreation.[2] The object of such precautions is the same with that of punishment, namely, the prevention of crime; inasmuch as they tend to impress the citizens with a sense of right, acting educationally upon them, like the virtuous principles which a good father instils into the minds of his children. Hence the science of police has been described by a contemporary authority, as "the moral education of a people towards self-government."[3]

It is pretty clear, that police, in this extended sense of internal polity, comprehends the protection of society against not only physical, but also moral evils. The regulation of the highways, and internal navigation; the care of the public health; poor laws or corn laws, may be classed under it with no less propriety than public instruction, or religious establishments. The true ground on which an established church is defensible, is, its value as an instrument of police in this elevated sense; and the same test is applicable to national education, and other institutions, affecting the moral welfare of society.

The present state of moral and political science is not such as to enable us to define police with anything like precision. But if what has been said, does not convey an accurate notion of that which it is, it may point more plainly at that which it is not. No one, for instance, will expect to hear of police in relation to the external defence, or foreign policy, of a state. Few will confound its objects with those of the dispensations of justice which are directed to the maintenance of private rights, or to the security of the state itself, as a social existence.

Limited definitio

The second, or limited definition, of police, considers it as that branch of the administration of justice, which operates directly for the prevention and detection of crime. It is the judicial function to hear and determine between right and wrong, and to sentence the offender to the punishment which the law has awarded him. But the judge cannot be brought into action, without an auxiliary power for securing the persons of offenders for justice; for checking crimes in the act of commission; and for watching the observance, or breach, of the laws. This is the *preventive* branch of justice; and the system of operations destined for the performance of these services, goes, in ordinary language, under the name of police. The object of such operations is of course included within those of the term police, in a larger sense, and preventive justice is therefore their more appropriate name. Under a good system of law, the powers, means, and ends, of preventive justice, would be carefully defined; so that they should, in no case, be confounded with those of penal or executive justice, nor the same individuals be employed in the performance of duties essentially different. But this important distinction has rarely been attended to as it ought, and the efficiency of police establishments has been thereby not unfrequently impaired. At the present time there is, we believe, no instance of the police of a large city which, as a whole, can be said to be merely a preventive system; but a variety of functions are associated under the name of police, contributing to the preservation of the public peace, health, and convenience, but the classification of which is, for the most part, defective. There are, therefore, few perfect systems of police, either in the wide or the limited sense which, it has been seen, properly belongs to that word.

Before we proceed to point out the essential requisites of a good police system, it will be useful to take a review of some existing institutions of this nature.

Ancient police re gulation

From the earliest times, all nations which have established regular laws, have had amongst them police regulations. They form a prominent part of the institutions of the ancient Egyptians and Greeks, and also of the Mosaic law. A special branch of the Roman law was applied to police. The Emperor Augustus, as is well known, introduced important changes into the police of the city of Rome, by withdrawing the powers previously exercised by the Prætors and Ediles, and constituting a magistrate under the title of *Præfectus urbis*, under whom were the *magistratus minores*, or *curatores urbis*, assigned for the protection of the several quarters into which the city was divided. In the reigns of Constantine, Theodosius, and Justinian, very severe laws were enacted against female prostitution. The capitularies of Charlemagne are remarkable for the heavy penalties they inflict upon the same offence, which seems also to have been a favourite subject of regulation with Saint Louis, and

Charles VI. of France. In 1502, we find police regulations established at Nuremburg, relating principally to the censorship of books; and there are extant, ordinances of police of the German empire, of the dates of 1548 and 1577, containing distinct ordinances for the empire, the circles, the counties, and the towns. Towards the end of the seventeenth century, the science of police acquired a new development, by the introduction into France of the system of secret police, to which we shall presently refer. There does not appear any particular advantage in detailing at length the police legislation of antiquity, or of the middle ages. It will, we think, be more instructive to confine our statements to modern times.

ld law of ngland.

The provision made for preventive justice by the old law of England, consisted in the powers which it vested in justices of the peace and constables, as also in individuals, when present at the commission of crime, or summoned by the hue and cry. The office of constable existed in the time of the Saxons, and the statute of Winchester (13th Edward I.) expressly directed that two constables should be chosen in every hundred; that suspicious night-walkers should be arrested and detained by the watch; and that in walled towns the gates should be closed from sun-setting to sun-rising. These are called high constables; in addition to whom petty constables were instituted for every town and parish in the reign of Edward III. and especially empowered by the statute 5th Edward III. cap. 44, "to arrest persons suspected of manslaughter, felonies, and robberies, and to deliver them to the sheriff, to be kept in prison till the coming of the justices." The hue and cry is the raising an alarm, and making continuous pursuit through the country, upon the commission of a felony, and was used as far back as the reign of Edward I., when it was comparatively easy by such means to discover a criminal flying from the law. At the present day, when the hue and cry is raised, every person, by command of the constable, is legally obliged, on pain of fine and imprisonment, to join in pursuit of the felon from county to county, or until they come to the sea; but it is now so rarely put in practice, that it may be considered as having almost fallen into desuetude. It is further an old rule of law, that every person present when a felony is committed, is authorized and required to arrest the offender. In early times, it seems to have been the custom for the freeholders of each county to elect "*de probioribus et potentioribus comitatus*," to be keepers of the peace; but the statute 1st Edward III., cap. 16, gave such appointments to the crown, by whom they still continue to be made. When the keepers of the peace became authorized by the statute 34th Edward III. to try felonies and misdemeanours, they acquired the title of justices; and their judicial functions have been so vastly extended by modern statutes, that the mere conservation of the peace is now by no means the most important part of their duties. Such were the ordinary courses available, under the law of England, for the prevention of crime, and for bringing offenders to justice.

As population and property increased, it was found that the ordinary magisterial and constabulary force became more and more inadequate for the public protection. It is not necessary to refer to the Newgate Calendar, or the life of Jonathan Wild, to prove the total absence of any effectual security to individuals, in the last century, against outrage and depredation. It is within the remembrance of persons now living, that a journey could not be undertaken from one part of England to another without risk of highway-robbery. The extent of crime in the metropolis at the close of the last century would be incredible, if it were not recorded upon respectable authority. Colquhoun, writing in the year 1800,[1] estimated the value of the property purloined and pilfered in various ways, in and about the metropolis, at two millions sterling in one year. Some of the instances given would now appear very curious.[2] The same writer furnishes a statement of the number of prisoners discharged from the metropolitan gaols and hulks in the eight years, 1792 to 1799, the total of which is 21,893, being, on an average, 2734 yearly; a very considerable number in proportion to the then population. The almost innumerable ramifications of crime in London, as detailed by Colquhoun, may excite surprise at the little effort that was made in any quarter before he wrote to repress it.

Police of London.

The public office in Bow Street was for some time the only place in the metropolis where a police magistrate sat regularly, without the jurisdiction of the city of London. Seven additional police offices were established in 1792, by the act 32d Geo. III. cap. 53, and the Thames police-office in 1798. Previously to their establishment, the magistrates of the county of Middlesex, and city of Westminster, acted as occasion required, in the same way as the magistrates ordinarily act in other parts of the country.

The constabulary force of the metropolis, comprising that of the cities of London and Westminster, the borough of Southwark, and parts adjacent, is stated by Colquhoun at 883; that consisting of the constables attached to the police offices and the Thames establishment, at 157; and, adding to these 2044 beadles, watchmen, and patroles, employed by the city, and by the numerous parishes and trusts, the civil force of the metropolis, available for purposes of police, amounted, in the aggregate, to 3084 men.

The Parliamentary Finance Committee of 1798, in their Twenty-eighth Report, took a general view of the Police Establishment, in reference principally to its expense; but although that committee recommended several important reforms, and, in the same year, the Government had under its consideration a proposition of Mr. Colquhoun for the establishment of a central police board, and other remedial measures, no result followed. The progress of crime and demoralization, however, began gradually to attract the attention of the Legislature, and Parliamentary Committees inquired into the subject of police in the years 1812, 1816, 1817, 1822, and 1828. At the latter date the necessity for a new system had become very urgent. The metropolis was subdivided into a number of petty jurisdictions, each acting independently, and frustrating the efforts of the other; the local functionaries were miserably inefficient; the absence of union in the constabulary power offered facilities to crime and disorder; and in the event of any real or anticipated tumult, it was necessary to preserve the peace of the town by a military force. In 1829, the act 10th Geo. IV. cap. 44, was passed, "for improving the police in and near the metropolis;" and pursuant to that act, a central office was established in London, and two commissioners appointed for the administration of a system of centralization, in lieu of the local functionaries. The metropolitan police district, according to that act, consists of about ninety parishes, and ultra-parochial places, in and surrounding the metropolis, comprising a population at present amounting to 1,515,592, but exclusive of the city of London and the river Thames. The active force employed under the commissioners at the close of the year 1837, was as follows:—

17 Superintendents at L.200 per annum each.
70 Inspectors at L.1, 10s. 6d. per week each.
342 Sergeants at L.1, 2s. 6d. per week each.
2992 Constables at 19s. per week each.

[1] *Treatise on the Police of the Metropolis*, by P. Colquhoun, LL.D., magistrate, &c. London, 1806, seventh edition.

[2] The following is one:—"The wife of a well-known sharper, lately upon the town, is said to have appeared at court, dressed in a style of peculiar elegance; while the sharper himself is supposed to have gone in the dress of a clergyman. According to the information of a noted receiver, they pilfered to the value of L.1700 on the king's birthday (1795), without discovery or suspicion."

Horse patrol.

The horse patrol, formerly attached to Bow Street, and recently[1] placed under the commissioners, consists of seventy-six men, mounted and armed.

Offices.

There are at present in London nine police-offices, to each of which three magistrates are attached. These are, Bow Street, Queen Square, Marlborough Street, Marylebone, Hatton Garden, Worship Street, Whitechapel, Union Hall, and the Thames Police. Constables are specially attached to each office, sixty-three altogether, besides twenty-two surveyors, and seventy river constables, belonging to the Thames police.

Expense.

The total expense of these establishments appears by the latest returns to be as follows:—

Metropolitan Police Establishment, exclusive of Commissioners' salaries, year 1837	L.209,754 [2]
Horse Patrol, do.	10,289
Salaries of two commissioners	1,600
Police-offices, including the River Force, (1835)	51,724 [3]
Total	L.272,367

The expenses of the metropolitan force are defrayed principally by a rate levied with the poor rate, upon the inhabitants. A certain proportion, however, is paid out of the consolidated fund; but the advances by the treasury are limited to L.60,000 per annum. The expenses of the nine offices, including the Thames service, and also the commissioners' salaries, are wholly defrayed out of the consolidated fund.

City police

The city of London is not included within the metropolitan district, but retains its separate police, acting under the municipal authorities. Upwards of 1000 persons are employed as marshalmen, watchmen, and constables, and the total annual cost is returned at L.43,862, of which L.34,924 was levied by rates upon the inhabitants, and the residue paid out of the city revenue.[4]

Functions of the metropolitan police.

The functions of the metropolitan police force are exercised under the control partly of the commissioners, and partly of the magistrates. They are distributed throughout the district in seventeen divisions, distinguished by the letters A to V. In each division there are one or more station houses, in which prisoners are lodged in the first instance, on their being given in charge, or taken into custody, until they can be brought before the magistrates at the police offices. Prisoners consequently remain in the station-houses during the night, and also during Sundays. When the case comes on before the magistrate, he deals with it as the law requires, either by discharging the offender, committing him for trial or further examination, convicting him summarily, or holding him to bail.

When a complaint is made to a police magistrate, he issues his warrant as he sees occasion, either to a constable attached to his office, or to one of the metropolitan force. The commissioners of police, although as magistrates they have the legal power to do so, are not in the habit of granting warrants; and the policemen cannot arrest without warrant, unless a charge is made, or an offence is committed in their presence. They have in fact little power beyond that of an ordinary constable, except that the police acts contain more express authority for the apprehension of suspected persons, than the laws which apply to the kingdom in general.

The means of detecting crime have been greatly augmented by the action of the central police establishment, but it may be doubted whether its operation is as efficient as it might be made towards the hindrance of crime, or the preventing its commission. Numerous receivers of stolen goods continue to carry on their business with impunity, and flash-houses still exist in the metropolis, where thieves are known to congregate to concert their plans. There are no authorised informers belonging to the police force.

The subjoined table, compiled from official returns, will shew the extent to which the central police force is brought into action in the course of the year.

Years.	Number of persons taken into custody by Police.	Number discharged by the Magistrates.	Number summarily convicted or held to bail	Number committed for trial.
1834	64,269	34,499	26,302	3,468
1835	63,474	32,544	27,817	3,113
1836	63,384	29,776	30,453	3,175
1837	64,416	33,043	28,345	3,028
Total	255,543	129,862	112,897	12,783
Average of the last four years.	63,885	32,915	28,228	3,196

The circumstance of more than half of the persons taken into custody, having been discharged without punishment, cannot fail to be remarked as indicating unnecessary detention to a serious extent. The remedy for this lies in an improved system of bail and recognizances.

Number of offenders apprehended.

Of the 64,416 persons apprehended in the year 1837, it appears that 5643 were charged with offences against the person, 180 with violent offences against property, 15,289 with larcenies and other offences against property committed without violence, 1727 with malicious offences against property, 884 with forgery and offences against the currency, and 40,684 with offences of a miscellaneous character. Of this latter class, it is worthy of remark, that 21,426 were charged with drunkenness, 3103 as disorderly prostitutes, and 6842 as reputed thieves, suspicious characters, and vagrants. It should be borne in mind that these offenders are exclusive of those apprehended by the city police, and the constables attached to the offices.

The police magistrates are occupied not only in the disposal of the offenders brought before them, but in some matters not of a criminal character, such as the administration of the poor-laws, and other duties conferred by particular statutes. A reference to Burn's Justice will shew the wide range of a magistrate's duty. They have some few, but very limited, powers, in civil cases. They act, in some measure, ministerially, in planning the detection of offenders, and shaping the evidence towards their conviction. There are, however, good reasons for desiring that the magistrates should be entirely confined to their judicial functions.

Vagrants.

The law of England has never entrusted the constabulary, nor has it armed the central police, with any general power of personal *surveillance* over the people. The law which is the most stringent against disorderly or suspicious persons, is the vagrant act,[5] which in fact authorises the magistrate to punish, without any direct proof of the commission of a crime; and the metropolitan police acts[6] have somewhat extended the description of persons who may be apprehended and dealt with as rogues and vagabonds, according to the first mentioned act. In so populous and wealthy a city as London, it is indispensable that summary powers should be vested in the magistracy for the protection of the public against those who live by depredation, and who have neither "a local habitation nor a name," as securities for their good behaviour. It is officially recorded that in the year 1837, the number of depredators, offenders, and suspected persons, within the *cognizance* of the central police, was 19,919, being in the ratio of 1 to each 83 of the population; and as the average length of the career of each offender is estimated at about four years, the danger to property from the existence of such a floating mass of crime is sufficiently apparent. Far from the apprehension of peril to the liberty of the subject, from a further extension of the summary powers of the magistrates, the better opinion seems at present to be, that they might be extended with advantage even to all cases of larceny.

mbling
es.

There are in London at present about thirty common gambling-houses known to the police, and the average number of persons daily resorting to each is about twenty. The police has not, however, any summary control over them, but they are subject to indictment by any common informer. Colquhoun reckoned forty-three gambling-houses, including seven subscription-houses of the first class, and supposed the yearly aggregate of money won and lost in them to be L.7,225,000. There are no means of knowing what may be the amount of play in the club-houses of the present day, but we entertain no doubt whatever that Colquhoun's estimate was altogether an exaggeration. The number of persons charged with gambling in London in the year 1837 was 366.

ical
ce.
stitu-
ti.

There exists no medical police in this country of the kind which we find specially established in some parts of the continent. The exercise of the medical profession is subject to conditions imposed by law. We have quarantine laws, under the superintendence of the officers of the customs revenue; and the laws which prohibit the sale of unwholesome food are rather enforced by the officers of markets, than by any branch of the police service. A Board of Health was appointed for a special purpose, during the late visitation of the cholera, but there has never been any permanent establishment of this nature. The inquiry, how far such an establishment would be expedient, suggests itself chiefly as regards female prostitution. The existing law only subjects prostitutes to punishment as in case of disorderly conduct, and houses of ill-fame are only liable to indictment, not to summary visitation. The consideration of protecting the public against the spread of diseases, has not hitherto entered into the policy of our legislation, so as to subject prostitutes to any medical visitation; nor are they restricted from walking the streets, or frequenting places of public amusement. We shall presently notice the very different way in which this matter is treated in France. In the mean time, it is satisfactory to mention, that the extent of prostitution in London is, in truth, nothing like that which the notions of some writers have formed of it. Instead of there being 50,000 prostitutes in the metropolis, as estimated by Colquhoun, the actual number known to the police in 1837 was as follows:—

Prostitutes,	well-dressed, living in brothels,.......	895
Ditto,	well-dressed, walking the streets,.....	1612
Ditto,	low, infesting low neighbourhoods,...	3864
	Total,.........	6371

The number of brothels, in which prostitutes are kept, was 933, having an average number of four in each; the number of houses of ill-fame to which they resort, 848; and that of houses in which they lodge, 1554. Such appears from the best authority to be the real state of the case.[1]

A daily police report of the proceedings, and of the informations received at the several police-offices, is printed for the use of the magistrates and officers; and an official newspaper, called the *Hue and Cry* or *Police Gazette*, is also circulated amongst the authorities, throughout the kingdom.

m-
ations
of ect
mittee.

During the sessions of 1837 and 1838, a select committee of the House of Commons, appointed on the motion of Mr. Hawes, inquired into the state of the metropolis police, and recommended various important improvements in its management. Amongst these are the consolidation of the several constabulary forces of the metropolis and the river Thames, including those of the city of London, under one authority; the confinement of the magistrates to judicial duties; the extension of their summary jurisdiction to all cases of larceny, and also to many civil cases; the augmentation of the officer's power to arrest; the improvement of the bail system; and the better regulation of the police-offices, with a view to the public accommodation. Our limits do not permit us to discuss the advantages of these reforms. Suffice it to say, that they are of the utmost importance to the efficiency of the police service; and that until they are effected, the metropolis will not be adequately protected against crime and disorder.[2]

Rural police.

The English rural police is of two kinds; that established in the principal cities and towns, and that of the rural districts properly so called. In the former case, it is exercised by the municipal magistracies, and the constabularies acting under them; in the latter, it is vested in the justices of the peace, and constables acting under the old law to which we have adverted.

The cities and towns in which a police has been established upon the same system as that of the metropolis, are, Liverpool, Bristol, Bath, Hull, and Newcastle-upon-Tyne. Other towns have their police, more or less efficient, but regulated upon plans of their own, either prescribed by the municipalities, or by local Acts of Parliament.

The only instance that we are aware of, in which a special rural police has been established in England, is in Cheshire, by an act passed in 1829,[3] entitled "An Act to enable the magistrates of the county palatine of Chester to appoint special high constables for the several hundreds or divisions, and assistant petty constables for the several townships of that county." This act has provided the county with a comparatively efficient constabulary, whose duties and conduct are prescribed and superintended with more accuracy and vigilance than in any other part of the country.

But, however efficient, within an isolated district, may be this or that police establishment, it will have little effect towards the prevention or hindrance of crime in the aggregate, unless a regular chain of communication be maintained throughout the country; unless vigilance be made to circulate; unless, in short, there be centralization. This consideration induced the Government to issue a commission, dated the 20th of October 1836, the commissioners under which were directed to inquire into the best means of establishing a constabulary force in the English counties, with an especial view to the prevention of offences, and with regard to any proceedings before trial by which the detention and apprehension of offenders might be rendered more certain; also to inquire into the public services which might be obtained from such a force, either in the preservation of peace, and due protection of property, or enforcing the more regular observance of law; and into the manner in which such force should be appointed and paid. At the time we write, the commissioners have not made their report, but there is reason to believe that a very valuable one will soon be produced.

Advantages of organization.

That it is perfectly practicable to organize a constabulary force for the whole kingdom, acting under a central authority in the metropolis, and governed by a gradation of superior and responsible officers, cannot be doubted. Nor is it much less clear, that the public morality, and the interests of property would be greatly promoted by such a measure. It especially deserves notice, that, in the rural districts, the delinquents are almost entirely of the vagrant class, being either habitual depredators, or vagrants asking alms. Now, the only law for the constant control of these habitual delinquents, is the vagrant act before cited, which experience has shewn to be by no means sufficient. Few offences are committed within the view of a constable; therefore the constabulary seldom acts but upon information, and as there is no special obligation upon any one to communicate information, the enforcement of the law is so far dependent upon chance. Then, the ancient practice of pursuit by hue and cry having fallen into disuse, the vagrant depredators referred to, go from county to county, taking up their temporary abode in common lodging-houses, the number of which has much increased of late years, and so pursue their career with impunity. Of the habitual depredators within the cognizance of the metropolitan police in 1837, 2712 were known to be vagrant; in Bristol 605 were so known; in Hull 303; and in Newcastle 454. From 18,000 to 20,000 vagrants are annually committed to prison throughout the country. They assume different names as occasion requires, and to identify them, or ascertain their real history, is usually a matter of great difficulty.

---

[3] 11th Geo. IV. cap. 97.

Expediency of placing discharged criminals under police control

One of the indirect means enumerated by Bentham for the prevention of crime, was a system of proper names, by which an appellation should be assigned to each individual, indicative of his family and birth-place, and distinguishing him from all other persons whatsoever. Bentham also recommended, in certain cases, the affixing marks on the skin, such as are imprinted by sailors on their bodies, with gunpowder, at the present day. The old law of England branded all laymen who had once been admitted to the benefit of clergy, by burning them with a hot iron in the brawn of the left thumb, in order to distinguish their persons for the future. Now, it is worthy of consideration, whether the rationale of branding is not still applicable to the cases of all offenders once convicted of crime? It is very desirable that all persons of suspicious character should, for a limited period after their liberation, be so distinguished from others, as to enable the police to have a knowledge of their movements. It is also desirable, for their own sake, as well as that of the public, that such individuals should, as far as possible, be kept away from immediate incentives to crime. To whatever perfection prison-discipline may eventually be brought, it is vain to expect that its reformatory influence can invariably be such as to subdue the frailty of human nature, and the seductions of present opportunities. The law of France has, therefore, as we shall presently show, placed the criminal, for a limited period after his discharge, under a certain *surveillance* of the *Haute police*, as a part of his punishment. The expediency of introducing such a system into the English law to any, and to what extent, is a point deserving of serious reflection.

Such a proposal must of course be understood as applicable only to persons actually convicted of offences. Any thing resembling a passport system for the whole population, innocent as well as guilty, would not only be incompatible with free institutions, but invincibly repugnant to the spirit and feelings of the British people. The question therefore resolves itself into one of punishment, the problem being to find that punishment, which having regard to the habits of the criminal, shall contain within it the maximum of prevention, combining the direct with the indirect method of hindering crime. Now, assuming, as the fact is, that imprisonment, according to the present system of secondary punishments, has not the qualities required, but is often neither deterring, nor reformatory, might not police-supervision be substituted, in some cases partially, in others entirely, for such imprisonment? Would not such police supervision be a peculiarly appropriate punishment for vagrants and other petty offenders, the terms of whose imprisonment are very short? and might it not be advantageous, even in the cases of graver offenders, to permit the commutation, under certain regulations, of a portion of the imprisonment, into police-supervision? We think that the principle of such alterations might be demonstrated to be beneficial, but then it would remain to be considered of what the proposed supervision ought to consist.

The liberated convict, who might be thus placed under police control, might properly be required to inform the police from time to time of his place of residence; to present himself to an officer periodically; to avoid all disorderly or tumultuous assemblies, and all places of public resort of a vicious character, to be specified to him by the police; not to enter any towns or districts, specially prohibited by the police, such as in many cases the metropolis, or other populous towns, or the localities of large fairs, or races, would be; and, above all, not to associate with other liberated convicts. Any breach of these conditions should subject the offender to summary imprisonment.

Such regulations might be objected to upon the one hand as too irksome, and, on the other, as not sufficiently stringent. It might be suggested to add to their severity, by prescribing absolutely the place of residence of the delinquent, by prohibiting him from all places whatever of public amusement, and the like. Care, however, must be taken not to draw the restraining cord so tight as to debar the convict from that which is harmless in itself, and may by possibility have a beneficial influence upon his character. But we acknowledge the difficulty of fixing the limits of restriction, a difficulty which occurs in every branch of police, and, until our knowledge of the science shall be advanced by experience, will continue to meet us at every step in legislation.

Whilst the formation of a general rural police in England is under consideration, it will answer little purpose to describe the nature of the constabulary, which now serves as a substitute for it. Its inefficiency is notorious. The fatal riot which took place at Canterbury[1] is a flagrant instance of the mischiefs which a single individual may bring upon society, when society has not taken measures of ordinary prudence for its own protection.

Scotland.

The constabulary of Scotland is under the control of the magistrates of the municipalities and counties, in the same way as in those parts of England where the principle of the central police has not been introduced. It is consequently wanting in almost all the requisites of an efficient system.

Ireland.

A regular police force was first established throughout Ireland under an act passed in 1814,[2] "to provide for the better regulation of the laws in Ireland, by appointing superintending magistrates and additional constables in certain cases." Several other acts followed, which were consolidated by the act of 1836,[3] and by this latter the constabulary is at present regulated. The lord-lieutenant appoints stipendiary magistrates and constables in the several towns, counties, and baronies in the proportions prescribed by the act, with an inspector-general and sub-inspectors for their superintendence. The following qualification for the constables is illustrative of the state of society in Ireland. They are required to be "of a sound constitution, able-bodied, and under the age of forty years, able to read and write, of a good character for honesty, fidelity, and activity, not a gamekeeper, wood-ranger, *tithe-proctor*, *viewer of tithes*, *bailiff*, *or parish clerk*, or a hired servant, or keeping any house for the sale of beer, wine, or spirituous liquors by retail." The stipendiary magistrates are fifty in number, with salaries varying from L.400 to L.1000 per annum. The office of inspector-general is considered as a highly responsible one; his salary is L.1500 per annum. The following is a summary of the total amount of police force employed on the 1st of January 1838; distinguishing the proportion of expenses borne respectively by the consolidated fund, and by the counties, cities, and towns, pursuant to the provisions of the act:[1]

8263			

It will be observed that the above force contains a variety of gradations of officers; and this is a principle of great importance in the organization of police establishments. It both regulates responsibility, and holds out the prospect of promotion as the reward of merit.

The lord-lieutenant is empowered to establish an additional special police force in any county or district declared to be in a state of disturbance. The peculiar condition of Ireland has rendered this provision requisite; but it is well known that it has not hitherto superseded the necessity of the large military force which, as an instrument of mere police, continues to be stationed in that country.

Dlin.

The City of Dublin has a special police force, with an office and two magistrates, acting for that metropolis and a certain surrounding district. Its powers and duties are analogous to those of the London central police; and it acts under the immediate authority of the chief secretary to the Lord-Lieutenant. It was established by act of Parliament in the year 1836.[2]

ks, &c.

There are, in various parts of the United Kingdom, officers possessing limited powers of police for special purposes, such as the police of docks, railways, &c. whose authority is defined by the particular statutes under which they act.

Fnce.

The nation, in whose history the operations of the police have been the most conspicuous, is modern France. A knowledge of the extent and effects of the police agency for the last century and a half is indispensable to a right understanding of French history, and there are ample materials for an elaborate work upon the subject.[3] Our present limits do not permit us to do more than trace superficially the origin of existing institutions.

orical
sch.

From the commencement of the feudal *regime*, the provost of Paris was the highest municipal authority. He not only carried the sword at the head of a military force, but presided in the robe of a judge at the Châtelet, that ancient and venerable building to which the administration of justice was so long wholly confined. One of the ten chambers, or courts, of the Châtelet, was that of police, to which reports were made of all infractions of the police regulations of the city. The provost had under him two officers of the second rank, called the *lieutenant-civil*, and the *lieutenant-criminel*, besides the judicial and ministerial staff of the Châtelet. There was also an independent police authority, called the *bureau de ville*, which took cognizance of all that related to the water, the quays, the ramparts, and the public festivals of Paris, and whose principal officer was styled the provost of merchants. For a long period, the parliament of Paris moderated these conflicting jurisdictions, and in 1667, their recommendations gave rise to the edict made by Louis XIV. in that year, whereby the functions of police were withdrawn from the civil and criminal lieutenants, and conferred on a new magistrate, who, under the name of *lieutenant de police*, became the representative of that jurisdiction which had previously been exercised by the authorities of the Châtelet. The *bureau de ville*, however, continued its functions as before. In 1674, the title of the new magistrate was declared by the king to be that of *Lieutenant-General de Police*, which continued to the Revolution.

The first of these officers was De la Reynie, famous for being charged with the execution of the edict which revoked that of Nantes in 1685. To him succeeded the Marquis D'Argenson in 1697, the creator of the system of secret police, which has ever since been more or less acted upon in France. D'Argenson employed *espionage* largely. He is described by Fontenelle, as having unparalleled powers of divination, and was undoubtedly a man of unusual sagacity. He had the merit of refusing to execute in Paris, the measures of persecution against the Protestants, which were being carried on in the provinces. The succeeding lieutenants-general were, Machault d'Arnouville (1718), Count d'Argenson (1720), Taschereau de Baudry (1720), Ravot d'Ombreval (1724), René Hérault (1725), De Marville (1739), Berryer (1747), Bertin (1754), De Sartine (1759). The activity of the last mentioned officer was very remarkable. He chose his inferior agents with judgment, and some curious proofs are on record, how accurately he knew all that was passing in Paris.[4] He was in the habit of furnishing to Louis XV. reports of a licentious character, describing the most scandalous indecencies committed in the capital, and a collection of them was found in the Bastille at the capture of that fortress-prison, in July 1789. The secret police was brought to great perfection by De Sartine, and he had his emissaries in every European state. He seems to have been both feared and hated by the people. The French police about this time excited the attention of other governments; and both the Empress Catherine II. of Russia, and Maria Theresa of Austria, having applied to the French government for information on the subject, De Sartine made for their use a collection of the ordinances and regulations then subsisting, which is still extant. An unfortunate event is recorded to have happened during De Sartine's administration, which is illustrative of the evils of conflicting jurisdictions in matters of police. A fête, with fire-works and illuminations, was held in the Place Louis XV. on 30th of May 1770, in celebration of the marriage of the Dauphin with Marie Antoinette. The responsibility of the arrangements was divided between De Sartine and the provost of Merchants, and the consequence was, that a scene of confusion ensued, in which 132 persons were killed, and as many wounded. The parliament reprimanded both functionaries, and additional powers were soon afterwards conferrred on the lieutenant-general. To De Sartine, succeeded Le Noir (1774), D' Albert (1775), Le Noir, (second administration 1776), and De Crosne (1785), who closed with the Revolution the list of lieutenants of police. Their office, and that of the provost of Merchants, merged in the *comité permanent*, who re-organized the municipality of Paris, and laid the foundation of the existing institutions, which take their origin principally from the legislation of the revolutionary period. The secret or *haute police*, was acted on, as is well known, by the General Directory, and afterwards, with terrible effect, under the Emperor Napoleon. The unfortunate Duc d'Enghien was one of its victims. The life of the celebrated Fouché, is full of interest and instruction under this head. Not the least remarkable circumstance in Fouché's career, is the fact of Napoleon having been in the habit of employing several branches of *contre-police*, to watch the proceedings of his own police-minister.[1] Thus, he had a distinct police of the palace under the grand-marshall, of the city of Paris under the military governor, and of all France under the inspector-general of *gendarmerie*. The *gendarmes* throughout France had to transmit daily bulletins of all that took place, for the information of the Emperor. The general police under Fouché was evidently considered by Napoleon as a sort of rival of the Imperial power.

Description of French system.

The law of France declares the police to be instituted "to maintain order and public tranquillity, liberty, property, and individual security." Its principal characteristic is declared to be "vigilance;" the objects of its solicitude are society *en masse*.[2]

It is divided into *administrative* and *judicial* police. The administrative has for its object, the maintenance of public order everywhere, and in every part of the general administration. Its tendency is to the prevention of crime, and it causes to be executed all public laws, ordinances and regulations. It is exercised throughout France by the minister of the interior, in cases of general measures. In the departments, and in the communes, it is under the direction of the *préfets*, *sous-préfets*, and *maires*, and in Paris, under that of the *préfet de police*. These magistrates may prescribe such measures as are not contrary to the existing law, and make such orders, in respect of local police, as circumstances may require, any infraction of which is punishable according to the penal code.

The *administrative* is subdivided into *general* and *municipal* police. The latter term includes also the *rural* police. The general administrative police, comprises the regulation of passports, mendicity and vagrancy, prisons and public institutions, the press, religious worship, seditious language, public provocation to crimes, defamation of authorities, desertion, &c.[3] To this head belongs the *haute police*, to which we shall presently advert. The objects of municipal police are the preservation of the public security, health, and tranquillity, in the public streets and passages, in regard to fires, inundations, the exchange, markets, theatres, and public places, the public edifices and monuments, the course of commerce, and collection of taxes.[4] It seems to comprise, with some additions, the functions of the ancient *bureau de ville*.

The *judicial* branch of police is engaged in detecting the perpetrators of the crimes and offences, the commission of which has not been prevented by the administrative branch. It collects evidence, arrests offenders, and delivers them to the tribunals authorised to try and punish them. It is exercised under the authority of the *cours royales*.[5] Although this branch is termed judicial, it would seem more correct to describe it, as that which secures offenders for justice, in contradistinction to the operations by which the act of crime itself is hindered from commission.

A special police service is established in the French ports, under the name of *police maritime*. All offences committed in ports or naval arsenals, whether committed by persons in the naval service or otherwise, are cognizable by the maritime tribunals established for the purpose. The crews of all ships of war in port, are amenable to these tribunals for all offences against naval discipline. Offences against maritime police are described to be; first, all such as are committed against public order, and the service of the arsenals, or in the contravention of the special rules made for the port; and, second, simple thefts below the value of six francs, committed in the arsenals. The penalties which the tribunals of police are empowered to inflict, are, imprisonment not exceeding three months, compensation under 100 francs, loss of wages, and expulsion from the service of the arsenal.[6]

The rural police of France is exercised by the *juges de paix*, and the mayors, under the superintendence of the *préfets* and *sous-préfets*, by the aid of *gendarmerie*.[7] The *préfets* are the chief magistrates of the departments, and are appointed by the king. The duties of a prefect are so comprehensive, as to have been thus described by a legal writer, "Surveiller, reparer, feconder, voilà sa tache." He watches especially over the property of the state, and the public security; the roads, rivers, and other objects of common use; and is the agent of all the operations of government in his department.[8] He has the power of requiring the aid of the officers of the judicial police, for all purposes relating to the prevention of crime. The rural police punishes thefts or injuries to natural productions, regulates gleaning, the fixing of boundaries between lands, the interment of dead animals, and a variety of matters affecting the cultivation of land, and likely to give rise to disputes amongst a population of small proprietors. Offenders against rural police are punishable by imprisonment, and by the enforcement of compensation, as amends for injuries done.

The principle of centralization, it will be perceived, exists in the rural police of France to a considerable degree. The mayors and local magistrates, being under the immediate supervision of the prefects, who are controlled directly by the Minister of the Interior, there are the means of obtaining a certain unity of action in its proceedings. But the chain of communication throughout France, for purposes of police, would probably be improved if the machinery were less complicated, and the number of subordinate functionaries were smaller. Complaints are frequent, in cases where local improvements or changes are required, or where individuals have to petition for the redress of a grievance, or for permission from Government to do some act, of the great number of hands through which such applications must pass, in order to their being consulted, before the requisite authority can be obtained. The public thus suffers inconvenience and delay, from the want of simplicity in the arrangement of the system. It is not in the administration of rural police, properly so called, that the French system suggests much worthy of consideration, but rather in respect of the Haute Police, whereby convicted offenders are brought immediately under official surveillance in all parts of the country. In Paris, the "préfet de police" is charged with the whole administration of his department.[9] As regards the municipality, he exercises all the functions of the mayors in the communes, but is subject to no other control than that of the Minister of the Interior. The expenses of the prefecture are charged upon the city of Paris, but its jurisdiction extends throughout the Department of the Seine. The prefect is empowered to make such regulations as he deems expedient, consistently with the existing laws. A summary of his functions will perhaps be the best mode of conveying a notion of the extent of police interference in the French metropolis.

In respect of the general police, it is at the prefecture that passports are issued to travellers, and are *visa'd* on their arrival at Paris. Travellers remaining in Paris more than three days require permission for that purpose. All public establishments for the relief of the poor, or charitable purposes, are subject to police inspection. The prefecture may arrest all vagrants and mendicants. It superintends the police arrangements of the metropolitan prisons, and appoints certain of their officers. It carries into effect the regulations in force relating to hotels, lodging-houses, gaming-houses, and brothels. It prevents tumultuous assemblies, and coalitions of workmen. It puts in force the laws affecting the press, and restraining indecency and obscenity; superintends the construction of theatres, and keeps order within them; attends places of worship to prevent disorders there; takes cognisance of the distribution of gunpowder, and the use of arms; arrests deserters, and makes the arrangements at public *fêtes.*

The duties of the préfet and his officers in regard to the *municipal* police, are still more multifarious than those of the *general.* The care of all roads and passages, not being the great roads of the kingdom, *(la petite voirie)* and of the shops and stalls; the construction of scaffoldings, and the demolition of ruinous buildings; are committed wholly to the prefecture of police. Thus the police causes the streets and gutters to be cleaned; seizes dangerous animals; regulates the speed of carriages; and prevents their stopping the way. It preserves health, as far as possible, by removing all filthy or noxious accumulations; takes measures to prevent fire; and secures the requisite supply of water to the city. It verifies weights and measures; enforces the regulations of the markets, baths, hackney coaches, pawnbrokers, and the numerous other places and things in Paris which are subject to special rules; guards from injury the public buildings, monuments, fountains, &c., and requires their repair, when needful, by the proper authorities. In short, there is scarcely any part of the *matériel* of society, which is not subjected to the supervision of the prefecture of police.
